Mr. J. W. D. BRADLEY (Engineer and Surveyor to the Westminster City Council) said that he had for twelve years conducted the execution of contracts for public lighting definitely based on a candle-power standard, and he did not hesitate to express satisfaction with these contracts, and his preference for that system over the surface illumination test. To give an intending contractor the candle-power he is required to supply, and the height above the street at which it was to be fixed (stating within limits the polar distribution), and reserving the right of approval of the general character of the lantern and its reflectors, supplied him with a definite practical problem to solve, and he could deal with it with much less trouble than if he had to consider the many points involved by the adoption of a minimum illumination value over a large area. He believed that he had been the first to specify a definite amount of measured light as a basis for tendering.

Mr. FRANK BAILEY (Chief Engineer, City of London Electric Lighting Co.), after expressing his complete approval of the draft specification, said he regretted that an attempt had been made by Mr. Abady at the last annual meeting of the Institu-

tion of Gas Engineers to prejudice the consideration of the draft specification by adversely criticising it in public, whilst it was still a confidential document.

The Chairman, however, remarked that he thought that the responsibility for this discussion rested with the Council of the Institution of Gas Engineers, and not with Mr. Abady.

Mr. E. ALLEN (Vice-President of the Institution of Gas Engineers) held similar views to the other representatives of the gas industry, and thought something might be done to act upon Prof. Morris's suggestion of taking into account something else in addition to minimum horizontal illumination.

Mr. ROGER T. SMITH (Great Western Railway Company) sympathised with the committee in their efforts to save time by the adoption of minimum horizontal illumination, and said that for his railway-station lighting he had adopted this plan, although he had also included diversity factor and a term for intrinsic brilliancy of the lamp in his own specification.

Mr. W. R. COOPER thought the objections to the use of minimum horizontal illumination were largely due to misconception. If minimum illumination, one great advantage of which was that it took advantage of every mortal thing, was not adopted, what was the alternative? He did not think the difficulty of taking candle-power only as the basis was appreciated, and thought the horizontal illumination on the street surface was the best.

Mr. JACQUES ABADY said he believed that, but for the criticism at the Institution of Gas Engineers, the specification would have been a *fait accompli* by now. Continuing, he expressed himself with great vigour against the specification, which he characterised as completely wrong from beginning to end. It set up, he said, a certain standard minimum, measured in a particular way, and then admitted that 80 per cent. of the streets could not be so measured. It was the candle-power that produced the horizontal illumination, and not *vice versa*, and therefore why not measure the candle-power? Mr. Harrison's table at the end of the specification was based upon theory run mad. Taking two lamps 100 ft. apart and 10 ft. high, they would have to have a candle-power of 95.5 in order to give a horizontal illumination of 0.01 foot candle. Supposing there was a badly-lighted street which it was desired to illuminate better. An electrical engineer might offer to supply 100-watt lamps which would give 95.5 candles. A gas engineer who worked upon the specification and the table would find that incandescent gas lamps of 43.8 candle-power on posts 20 ft. high and 100 ft. apart would give the same minimum horizontal illumination as the electric lamps of 95.5 candles on posts 10 ft. high. This appeared to him absurd. Again, assuming lamps 10 ft. high and 100 ft. apart, according to the table they would have to be 95.5 candle-power, but if they were moved only 10 yards further, then the illuminating power would have to be more than doubled. Could it be said that the lighting of a street under these two sets of conditions would be the same? The 200 candle-power lamps would, of course, be very much better than the 95 candle-power lamps, and yet the table showed them to be equal.

Mr. LEON GASTER explained that it was not intended that the draft specification should be adopted before it had been openly discussed at a joint meeting of all concerned.

Mr. A. P. TROTTER briefly replied to the discussion. With regard to Mr. Abady's remarks that minimum horizontal illumination was absurd, he referred him to the report of the surveyors in the Paper, who drove through the streets and classified them into three classes. The photometrists went out and made measurements which fell into exactly the same classes as the surveyors found. He would like to hear anybody explain that away. He was sorry, he said, that, after all the trouble he had taken, that he had not yet been able to convey to Mr. Abady what illumination really meant.

We have received a long letter from Mr. K. Edgcombe referring to some remarks made by Mr. Goodenough to which Mr. Edgcombe had not the opportunity of replying, as he had already spoken in the discussion. What Mr. Edgcombe wishes in particular to make clear is that his being now in favour of the draft specification did not imply that he had changed his views since writing an article in 1907 that had been quoted by Mr. Goodenough. Mr. Edgcombe points out that in that article he distinctly stated that it was the average horizontal illumination that mattered. He was still strongly of that opinion, although he was not in favour of making the statement of either maximum or average illumination compulsory in a specification.

**Meter Approved.**—The Board of Trade has approved the Bat meter, type H.T.R., for use on the two-wire continuous-current system.

**Manchester Local Section of the Institution of Electrical Engineers.**—The annual report records the holding of twelve meetings during the past session and the annual dinner. The membership of the Section is now 812 (including 22 graduates and 197 students), an increase of 27 over last year. The constitution of the Committee for next session was given in *ELECTRICAL ENGINEERING*, April 24th, page 236. The Manchester Students' Section has held eight meetings and three visits to works.

### THE STRENGTH OF OSRAM LAMPS

THE motor car illustrated in Fig. 1 is used by the General Electric Co. (India), Ltd., for business trips to mills and factories within a radius of thirty miles of Calcutta. There are over fifty mills in this area, in every one of which Osram lamps are installed in considerable numbers. Not-

FIG. 1.

withstanding the fact that the vibrations to which the Osrams are subjected in these places are abnormal, no complaint of excessive breakage has been received. The case shown at the rear of the car contains samples of various types of Osram lamps. During a period of nine months the same sample lamps have been carried daily, and throughout this period only one has suffered through breakage of its filament. When it is remembered that the roads in India (as witness the illustration above) are extremely rough, it will be appreciated that the very strongest filaments are required to withstand the continual jolts and jars.

FIG. 2.

on the current, and immediately lit up, evidently being none the worse for its strange encounter.

**Tata Hydro-electric Power Supply Company.** We are given to understand that the total capacities of the motors and transformers to be applied to the textile mills and flour mills in the Bombay district, which are to derive their power from the mains of the above company, will exceed 36,000 h.p. for the motors and 40,000 k.v.a. for the transformers. At the present time, twenty-seven textile mills and two flour mills are to be electrified, and the whole of their equipment is being manufactured by the British Westinghouse Company. It includes, besides motors and transformers, the complete control gear for each mill.

### AN ELECTRIC KITCHEN

SOME three months ago Simplex Conduits, Ltd., equipped an electric kitchen in connection with their office staff dining club in Birmingham. The time is yet early to have secured any very exhaustive figures as to cost, but the records so far secured have already borne practical results, whilst the experience gained is proving exceedingly useful and clearly demonstrating that electricity can more than hold its own from every point of view for cooking, even on a more extensive scale than is required in the average household. Some forty meals are prepared per day,

SIMPLEX STAFF DINING CLUB ELECTRIC KITCHEN.

consisting of soup, at least two kinds of joints, a choice of sweets, coffee, &c., and in addition some sixty teas per day. The records of cost so far secured may be regarded as distinctly satisfactory, in view of the fact that they include the heating of all the "washing up" water, and that the cook has had no previous experience of electrical methods. The average cost per person per meal has proved to be a fraction of a halfpenny, with current at one penny per unit. The kitchen is being used to test articles of standard manufacture in actual practice rather than obtain results from the use of a large elaborate cooking range. The cook has become a firm convert to electric cooking and fully appreciates the advantages of the "Plexsim" Cooker, a large size of which is in constant use. So far there has been freedom from breakdown of the actual elements, the only mishap being a broken connection to the grill on a cast-iron oven. A view of the kitchen is reproduced.

### PETITION FOR REVOCATION OF PATENT

A PETITION brought by Peto & Radford, Ltd., for revocation of Patent No. 3,549,11 for a switch for motor-car lighting circuits, granted to Van Raden & Co., Ltd., and M. Metz, was heard on Monday last in the Court of the Comptroller-General of Patents. The petition was held to have failed.

The title of the patent specification is "Improvements in Methods of and Apparatus for the Electric Lighting of Motor Cars and for other Purposes." It is stated that the object of the invention is to provide a switch for controlling certain circuits from storage batteries. There are ten claims and seventeen figures. It was urged by Peto & Radford, Ltd., represented by Mr. Courtney Terrell, that the patent should be revoked under Section XI. c. of the Patents Act, 1907, on the ground of insufficiency of description of the invention (not the description of the apparatus), the insufficiency alleged being that the switch, as well as the circuit connections, were claimed, although the switch itself was old. An identical switch, with the exception of the "off" position, was said to have been described in Specification No. 13,903/06 by W. A. Stevens for the control of a petrol-electric system. There was no invention, said Mr. Terrell, in incorporating a separate switch for the "off" position into the circuit-controlling switch in the way it had been done by dividing an existing contact. The only novel parts were the circuit connections. The patent as it stood was too broad. Van Raden & Co., he said, had been threatened with an action for infringement, but their switch was not the same, and was not used for the same purpose. That was how the patent had been brought to their notice, and they petitioned for its revocation. Mr. J. Hunter Gray, who represented Van Raden & Co., objected to prior specifications being cited on the ground for revocation chosen, but after some discussion this was allowed in accordance with the Comptroller's previous practice in some cases. However, Mr. Gray's argument that the switch described was a new switch was upheld, and the petition was dismissed.

# QUESTIONS AND ANSWERS BY PRACTICAL MEN

## RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelopes.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,338.

What are the most sensitive and reliable high resistances suitable for use in a thermal detector for wireless, and how may they be cheaply constructed?—P. P.

(Replies must be received not later than first post May 15th.)

### ANSWERS TO No. 1,336.

Please give the best method of semi-indirect lighting of offices arranged as follows:—Room, 63 ft. by 23 ft. by 14 ft. high; six double desks across the room, each at present with six 32-c.p. tantalum lamps; height of lights over desks are 2 ft. Desk centres, 9 ft. 3 in.; height, 3 ft. 6 in.; lengths, 19 ft.; passage down one side, 4 ft.; ceiling whitewashed; end walls dark green; large windows at each side of room. There are no obstructions such as pillars. Compare cost of installing and current consumption with B.O.T. unit at 1d.—"MAN."

The first award (10s.) is made to "W. L. G.," whose reply is given in slightly abbreviated form below:—

I would suggest the following scheme of semi-indirect lighting for the office in question. I gather the existing conditions consist of thirty-six 32-c.p. tantalum lamps arranged in rows of six over each desk, the total candlepower being 1,152, and, assuming a lamp efficiency of 1.7 watts per c.p., a consumption of 1.95 units per hour, practically 2 units per hour. The existing candle-power per sq. ft. of area works out at 1.26 c.p., which is somewhat high according to the various tables given in text-books, and has doubtless been found to be too severe. The object of semi-indirect system of lighting is to reflect most of the light on to the ceiling, at the same time allowing a certain amount through the opal bowl in the form of direct light. With the fittings suitably spaced, a most comfortable and soothing effect is at once apparent and with the absence of "glare." Having regard that the scheme is for office lighting, and doubt-

FIG. 1.

FIG. 2.

less economy of working is essential, I would suggest that over each desk be installed two semi-indirect fittings, fitted with 16-in. diameter opal bowls arranged as in Fig. 1, each fitting to be of 100-watt capacity, the lamp to be of the tungsten type having an efficiency of 1.25 watts per c.p. The fittings should be arranged 10 ft. from floor to brass bowl rim, with 4 ft. suspension from ceiling (see Diagram 2). Each fitting should have its own local switch for economy of working. This arrangement will give an illumination of 2.5 to 3 foot-candles on the desks. Good practice for direct office lighting is to allow 0.5 c.p. per sq. ft. of area, and add, say, for loss in semi-indirect system, 20 per cent., as

the walls are dark. In comparing the cost of installing, the wiring per point will be identical; the only difference will be the extra cost of the fitting, which is, roughly, five times greater than an ordinary plain office pendant with opal shade. In regard to current consumption, the system would take 1.2 B.O.T. units per hour with tungsten lamps; and here I would point out the saving effected is really due to the adoption of higher efficiency lamps and a reduction in the illuminating power, as the existing system appears excessive.

The second award (5s.) is made to W. D. Douglas, for a reply which is given somewhat condensed below:—

In this case, the work being presumably of a clerical nature, an intensity of 4 candle-feet on the working plane may be taken as a satisfactory allowance. The area of the working plane may be taken as 60 ft. x 21 ft. = 1,260 sq. ft.; therefore, the amount of effective light needed, measured in lumens (area in square feet x by intensity in candle-feet), is  $1,260 \times 4 = 5,040$  lumens.

With most commercial semi-indirect fittings about half the light will fall on the reflector, and about 45 per cent. will reach the ceiling direct. Of the former amount, about 50 per cent. (25 per cent. of the total) will be reflected, 40 per cent. (20 per cent. of the total) transmitted, and about 10 per cent. (5 per cent. of the total) absorbed. The total amount of light falling on the ceiling is thus 70 per cent. Of this, about 55 per cent. (38 per cent. of the total) will reach the working plane, allowing for the darkening of the white ceiling with time. Of the light transmitted through the reflector bowl (20 per cent. of the

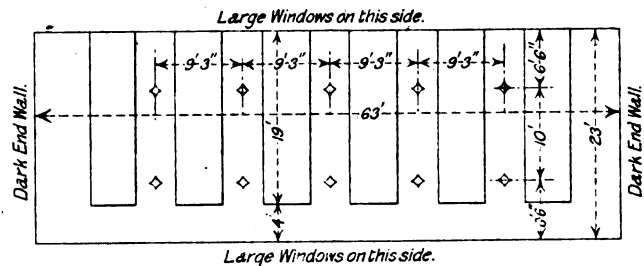

FIG. 3.

total), about 15 per cent. of the total will reach the working plane. Thus out of the total amount emitted by the assumed light source,  $38 + 15 = 53$  per cent. will be available for illuminating purposes. Therefore, the total light emitted by the lamps must be 9,520 lumens. A 40-watt tungsten lamp gives 323 lumens; therefore, thirty 40-watt lamps will be sufficient. The Holophane prismatic semi-indirect form of reflector has been assumed. If a less efficient reflector bowl is used, the intensity on the working plane will be correspondingly reduced. A good arrangement would be to have ten reflector bowl fittings, each to take three 40-watt lamps. These should be mounted in pairs centrally over the spaces between the desks, i.e., 9 ft. 3 in. apart. This permits of easy access for cleaning the bowls, which should be done frequently; and it must be remembered that the majority of the light is being reflected from the ceiling, which removes the necessity for having the bowls over the desks. This disposition leaves a space of 13 ft. between the last pair of bowl fittings and the end walls. This has the advantage that the intensity of light on the ceiling will shade off, making less of a contrast with the dark end walls, and the intensity on the end walls themselves will be low, both of which conditions will tend to provide a slight rest for the eye when it is raised from its work. The bowl fittings should be suspended 2 ft. 6 in. to 3 ft. below the ceiling. The installation of this system should almost halve the operating costs, its consumption being 1,200 watts, or 1.2 B.O.T. units per hour, against 2,300 watts, or 2.3 B.O.T. units per hour with the local lighting. At the very low rate of 1d. per B.O.T. unit, this would represent a saving of 1.1d. per hour. The cost of installation, including fittings and labour, would probably be about £12 10s., but this would vary with local conditions.

**The Imperial College of Science and Technology.**—The London County Council announces that it is prepared to award a limited number of free places at the Imperial College of Science and Technology for the session 1913-14. No restrictions as to income are prescribed, there is no written examination, and the places are awarded for one, two, or three years on consideration of the past records of candidates. Application forms may be obtained from the Education Officer, L.C.C. Education Offices, Victoria Embankment, W.C., and must be returned not later than Saturday, May 24th, 1913.

### A NEW PROPELLER FAN

WE have received particulars from the Wilson-Wolf Engineering Co., Ltd. (Thornton Road, Bradford), of their new "Polar" propeller fan, illustrated below. This is a medium-power fan running at a slightly higher peripheral speed than the corresponding sizes of the same firm's "Arctic" fans, and discharging about 10 per cent. less air.

Owing to the higher speed, they are fitted with smaller motors, and in consequence their prices are lower. A feature is that the blades are reversible, so that, to change the direction of the discharge air, it is only necessary to reverse the direction of rotation. The rings are circular and can be quickly fixed, and the motors are dust-proof and fitted with combined thrust and journal ball-bearings.

### INSPECTION LAMPS FOR MOTOR CARS

SOME useful new patterns of inspection lamps for motor cars have been brought out by Simplex Conduits, Ltd. (116 Charing Cross Road, W.C.). One of these is the lamp illustrated here, which is sold at the low price of 4s. 6d., including a 4, 6 or 8-volt lamp and three yards of flex. It is strongly made in brass and is provided with a substantial guard, a suspension hook, and a cord grip at the top to prevent the wire pulling out. A more elaborate pattern has a glass globe over the lamp and an arrangement of three brass legs for standing the lamp upright. A guard can be fitted over the glass globe, constructed so that the legs or hook can be used at either end.

**A Water Power Scheme with 5,412-feet Head.**—The scheme which is now in hand for utilising the water power of the lake of Fully, near Martigny, Valais, Switzerland, will employ the highest head of water that has yet been used, namely, 5,412 feet. The scheme has been worked out by M. Boucher, of Lausanne, the orders for the material have been placed, and the work has commenced. The pipe line has to withstand a pressure of 2,425 lbs. per square inch at the lower end, and special construction was necessary. The pipe line in a length of about 2½ miles consists of pipes with inside diameters of 19½ in. and 23½ in., and thicknesses of from 1½ in. to 1¾ in. The pipes of the upper section will be of the water-gas lap-welded type, whereas those of the lower part will be seamless, drawn from a steel ingot. The turbines for 15,000 h.p. will be built by Piccard, Pictet & Co., of Geneva, and the construction of the pipe line is in the hands of Thyssen & Co., at whose works at Mülheim (Ruhr) the pipes are being constructed.

### PROFESSOR C. F. DUSSAUD'S "COLD LIGHT"

A DEMONSTRATION of Professor C. F. Dussaud's "cold light," which has been much referred to in the French, and also the English Press recently, was given at the offices of Messrs. Louis Schloss & Co., 3 Rangoon Street, Crutched Friars, last week. Briefly the method consists in employing incandescent lamps with drawn tungsten filaments which are enormously over-run, and alternately switched on and off. We gathered from conversation with the inventor, that lamps run at 150 per cent. excess voltage, and alternately switched on and off from forty to fifty times a second, will last several hundred hours, but we were unable to ascertain the relation between the length of the period of incandescence and rest which results in this enormous difference between the life of the lamp used in this manner, and one over-run with ordinary alternating current, or whether it is merely the substitution of intermittent for alternating current which produces the long life claimed. In an alternative arrangement the frequency of interruption of current is lower, but three lamps are employed which are successively lighted so as to give a continuous effect without flicker.

Professor Dussaud proposes to use his system, among other things, for lighthouse work, but with a less frequency of interruption, by simply arranging that the revolving lamp shall be automatically switched off when turned away from the sea. For cinematograph work he also proposes to arrange a revolving contact maker on the shaft of the apparatus, so that the lamp is only alight (about 150 per cent. over-run) for the fraction of a second in which each picture is at rest, and is then extinguished during the time taken for the following picture to take its place. The lamp would thus be lighted sixteen times in a second, and would be alight for three-quarters of each sixteenth of a second and extinguished for one quarter. In this case, of course, Professor Dussaud does not expect that the lamp will have a very long life, but he considers that the saving in energy and apparatus will more than compensate for the cost of lamp renewals, and there is the additional advantage that the temperature of the bulb practically does not rise at all, so that there can be no danger of setting fire to the film. It is the high efficiency of an over-run lamp, and in consequence the relatively small heat production, compared with an ordinary lamp, which is accountable for the name "cold light" which Professor Dussaud has given his system.

### CORRESPONDENCE BURGLAR ALARMS.

*To the Editor of "ELECTRICAL ENGINEERING."*

SIR,—Referring to the diagram on your "Questions and Answers" page in to-day's issue, the magnetic switch therein is obviously shown diagrammatically, not as actually constructed. Now as small magnetic, or, more correctly, electrically-operated switches for use on low-voltage circuits and small currents are not very common items, it would be interesting if "Alarm" would say what make of switch he uses. I can only call to mind one make, and this is double-pole and of rather unwieldy construction.

Yours faithfully,  
W. PERREN MAYCOCK.

West Norwood, April 24th, 1913.

We have also received a letter from Mr. C. W. von Roemer, pointing out that the diagram of connections which "Alarm" gives is not correct as it stands, for, owing to the use of a common terminal, the switching on of any of the three lamps by its own switch would also light the other two lamps as well. Instead of the single set of contacts on the magnetic switch, three sets of contacts would be necessary if three lamps are to be lighted automatically when the alarm is actuated.

### THE "POINT FIVES."

*To the Editor of ELECTRICAL ENGINEERING.*

SIR,—I have been asked to make it quite clear as to the persons entitled to attend the above meeting during the M.E.A. Convention week on June 17th. On behalf of the Association I would like to say that it was the wish of our members at the Bradford meeting that any persons interested in pushing the use of electricity for domestic purposes would be welcomed, whether manufacturers, other technical men, or laymen. In order that the Committee may make arrangements for the place of meeting, it is necessary that all who propose to attend should let me know not later than May 22nd.

Yours, &c.,  
A. H. SEABROOK, Hon. Sec.

19 York Place, Baker Street, W.  
2nd May, 1913.

## STEPNEY AND THE B.E.A.M.A. GENERAL CONDITIONS

THE Stepney Borough Council has, on the recommendation of Mr. W. C. P. Tapper, the Borough Electrical Engineer and Manager, accepted Messrs. Escher Wyss & Co.'s tender for two 5,000-kw. turbo-alternators at a price of £38,031. This tender was so much below the next lowest that in all probability it would have been accepted in any case, but it may be noted, however, that all the British firms tendering refused to accept the Stepney Borough Council's general conditions, and tendered only to the new general conditions of the British Electrical and Allied Manufacturers' Association, to some clauses of which objection was taken by the Borough Council. One of these clauses, we understand, would absolve the contractors from penalty for delay due to "unusual inclemency of weather, civil commotion, general or local strikes or lock-outs, combinations of workmen, or in consequence of fire, or of any accident in the manufacture of important parts of the plant, or of any accident to or breakdown of important parts of machinery in the contractors' or sub-contractors' premises."

Another clause to which objection was taken is that relating to the time of taking over the plant. It appears that according to the B.E.A.M.A. conditions the contractor can give the engineer two months' notice that the plant is ready, and unless the engineer puts in an objection the plant is regarded as having been automatically taken over.

The amounts of the tenders were as follows, some firms having tendered for different makes of condensing plants and alternators in connection with their engines. Where not otherwise stated, the speed is 1,500 r.p.m.

Escher Wyss & Co., £38,031; Dick, Kerr & Co., £41,215; Richardson, Westgarth & Co., 7 tenders from £41,223 to £45,345; Willans & Robinson, 8 tenders from £41,089 to £49,130, and 2 tenders (£43,570 and £44,850) at 3,000 r.p.m.; Belliss & Morcom, 3 tenders from £43,195 to £46,573; Brush Co., £43,500 at 3,000 r.p.m.; J. Howden & Co., 5 tenders from £41,665 to £45,679; C. A. Parsons & Co., 4 tenders from £45,591 to £47,434, and one (£41,495) at 3,000 r.p.m.; British Westinghouse Co., £47,627; B.T.H. Co., £47,750; Oerlikon Co., £50,091 and £50,430.

## THE COAL SPECIFICATION OF THE ASSOCIATED MUNICIPAL ELECTRICAL ENGINEERS (GREATER LONDON)

A MODEL specification and conditions of contract for the purchase of coal for electricity works has been drawn up by the Associated Municipal Electrical Engineers (Greater London) and approved as a fair specification by the Society of Coal Merchants. Copies are available at a price of 10s. from the Hon. Secretary, Mr. E. S. Calvert, Electrical Engineers' Office, Finchley, N. A standard form of advertisement for tenders is proposed, and the general conditions are long and evidently carefully thought out. The general idea of the specification is that tenders may be invited alternatively for "named coal," that is, coal from a known pit, of a particular class and size, as specified by the colliery, or for "guaranteed coal," that is, coal which is to come up to certain standards of calorific value, moisture and size, as defined in a table attached to the specification. Thus, to take one example out of the eighteen classes of coal scheduled, "Semi-bituminous and pseudo-anthracite Welsh washed large nuts are to have a calorific value of 14,300 B.Th.U. per lb., moisture not exceeding 5 per cent. and not more than 15 per cent. is to pass through a  $\frac{1}{4}$  in. square mesh sieve. The specification sets out the method of taking samples, and requires that the tests of calorific value are to be taken by the Mahler Bomb calorimeter. The tenderer is to be allowed to nominate experts, to be approved by the purchaser, in case of dispute. Perhaps the most important part of the specification is the scale of bonuses and penalties, which provide within certain limits for increase or decrease of the price in direct ratio to the calorific value. There are also adjustments of price dependent upon the percentages of moisture and small coal, and the purchaser is to have the right to reject the consignment altogether if it is more than  $7\frac{1}{2}$  per cent. below the calorific standard, if the moisture exceeds  $1\frac{1}{2}$  times the standard percentage, or if the proportion of small coal as defined in the schedule for that particular class of coal exceeds 25 per cent. by weight. Forms of schedule for tenderers' prices are appended to the specification.

## CATALOGUES, PAMPHLETS, &c., RECEIVED

**TELEPHONE AND TELEGRAPH CABLES.**—A finely printed and useful catalogue of telephone and telegraph cables has been issued by W. T. Henley's Telegraph Works Co., Ltd. (Blomfield Street, London Wall, E.C.). It occupies 138 large and well-illustrated pages, and covers every type and almost every useful size of dry-core cable, as well as rubber-insulated and pure rubber aerial cables, cables and wires for internal telephone work, and all accessories. The greater part of the book relates to multiple cables, and besides the ordinary dry-core multiple telephone cable, the "quad" type, screened telegraph cables and subaqueous cables are dealt with, among others. Useful notes on testing and jointing are included, and a page is devoted to the subject of loading telephone circuits. The dimensions throughout are given both in the British and metric system. Every telephone engineer should obtain a copy of this list, as it cannot fail to be of service to him.

**AIR COMPRESSORS.**—A well-illustrated catalogue from Isaac Storey and Sons (Empress Foundry, Cornbrook, Manchester) deals with Scott's patent air compressors, of which they are sole makers. The main features of these compressors are the measures taken to ensure small clearances, efficient cooling and inter-cooling, and the particularly quick acting and reliable valves of the multiple-ball type, entirely without springs and requiring no valve pockets.

**INTERCOMMUNICATION TELEPHONES.**—The Sterling Telephone and Electric Co., Ltd. (200 Upper Thames Street, E.C.), describe the "Primax" intercommunication telephone system in a new pamphlet.

## ELECTRIC TRACTION NOTES

Arrangements are now complete for the Congress of the Tramways and Light Railways Association at Blackpool on June 12th and 13th. The headquarters will be the Imperial Hydro Hotel. On the Thursday, after a reception by the Mayor and Corporation and the Blackpool and Fleetwood and Blackpool and St. Anne's Tramway Cos. Papers by Mr. E. H. Edwardes, on "Possibilities for Increasing Profits on Inter-urban Lines," and by Mr. F. Bland, on "Tramways, a *Résumé*," will be read. The Papers down for Friday's meeting are "Railless Traction and Motor Buses," by Mr. H. England, and "Standard Rules for Motormen and Conductors," by Mr. A. V. Mason. Excursions are arranged for both afternoons, a banquet will be held on Thursday evening, and a dance on Friday evening.

The Metropolitan Electric Tramways (Railless Traction) Bill has been passed by a House of Commons Committee presided over by Sir Ivor Herbert. The Bill provides for linking up the Middlesex and Walthamstow electric tramway systems between Wood Green and Walthamstow, over a route for which the Metropolitan Electric Tramways, Ltd., had powers to construct a tramway, but which it was not thought would be financially successful. One of the conditions attached to the Bill is that a bridge over the River Lea shall be widened. The question of a contribution towards road maintenance did not arise in this case, as the company has a working arrangement with the Middlesex County Council with regard to tramways in the greater portion of Middlesex.

The Finance Committee of the Manchester Corporation has pointed out that, on the basis of 5 per cent. on capital expenditure, the Tramways Department should contribute £103,117 to rate relief for the past completed financial year. The Tramways Committee, however, have protested against a larger sum than £100,000 being allowed, which sum was provided for in the annual estimates. The Corporation are to be asked to sanction a visit by the General Manager and Permanent Way Engineer to London, Glasgow, Paris, Berlin, Hamburg, Vienna, New York, Boston, Philadelphia, Chicago and Toronto to study methods of passenger transportation.

Mr. Harry Lawson has given notice that on the second reading of the L.C.C. (Tramways, Trolley Vehicles and Improvements) Bill he will move that the Select Committee be instructed to insert a provision making the running of trolley vehicles subject to the provisions of Section 23 of the L.C.C. (Electrical Power) Act, 1900. This section is the one which gives the Borough Councils veto over the system of traction to be adopted, and has been used in several parts of London as a means of preventing the use of overhead wires.

## "ELECTRICAL ENGINEERING" PATENT RECORD

*(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)*

### Specifications Published May 1, 1913

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

24,122/11. **Power Transmission.** H. B. VAN DAALLEN and H. P. SCHREIBER. For power transmission from a prime mover two independent armatures are mounted in a single stationary field, the intensity of which can be varied at different points. Five figures.

430/12. **Operation of Track Points of Telfer Tracks.** R. P. STRACHAN and STRACHAN & HENSHAW, LTD. The switches or points are controlled from the telfer cab. They are worked by an electric motor through an eccentric or crank, and the motor is braked near the end of the stroke of the crank. Six figures.

8,682/12. **Geysers.** C. R. BELLING. The general arrangement of the spiral type described in ELECTRICAL ENGINEERING, Vol. VIII., p. 324, June 13th, 1912. Two figures.

9,981/12. **Manufacture of Drawn Tungsten Wires.** C. H. FISCHER. Pure anhydrous tungstic acid is reduced by a hot current of hydrogen in the presence of a volatile drying agent, e.g., phosphorus pentoxide. The crystals of tungsten which are formed are separated out, cooled, pressed into flakes, and then agglomerated, by pressing and simultaneously heating, into rods, which are then rolled in a machine which applies pressure at more than two points. Three figures.

19,014/12. **Wireless "Calling-up."** F. JAMIESON. Selectivity is obtained by using a continuous wave train from the transmitting station, which lasts a given time for each station. The receiving stations are fitted with clockwork, which starts up on receipt of the first wave, and runs until the wave train ceases, but only that station which is tuned for the exact time of the wave train is called up. This is obtained by the construction of a switch controlled by the clockwork. Four figures.

### Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad. Summaries of some of the more important of these patents will appear in our next issue.

**Arc Lamps:** SCHUER [Flame arcs] 10,496/12.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** KETTERING [Storage systems] 3,794/12; WESTERN ELEC. (*Western Elec.*) [Cables] 9,509/12; MARKS (*Reinert*) [Supporting of insulators for conductors] 10,805/12; METAL JOINTING CO. and HARDEN [Carrying metal-sheathed cables through bulkhead partitions] 10,989/12; DE STEFANI [Protective apparatus] 22,129/12; MARKS (*Brown, Boveri*) [Parallel working of synchronous machines] 24,097/12.

**Dynamos, Motors, and Transformers:** BROWN, BOVERI [D.C. transformation] 6,550/12; ROSENBERG [Synchronous machines] 9,644/12; BROWN, BOVERI [Phase compensation in induction machines] 10,113/12; WESCOTT [Current transformers] 28,967/12.

**Electrometallurgy and Electrochemistry:** MARKS (*Patents Purchasing Co.*) [Arc furnaces] 8,791/12; STEYNIS [Manufacture of ozone] 19,146/12.

**Heating:** KISSHÁZY [Vulcanisers for tyres] 1,579/13.

**Ignition:** STURGEON [Setting timing gear] 26,443/12.

**Incandescent Lamps:** DEUTSCHE GASGLÜHLICHT (Auer-Ges.) [Wire drawing] 11,439/12; SCOLLAR and DICK, KERR [Filament manufacture] 11,455/12; BAUM [Metal filament holders] 16,865/12; WESTINGHOUSE METALLFADEN GLÜHLAMPENFABRIK [Treatment of metals or alloys to render them ductile and malleable] 19,283/12.

**Instruments and Meters:** MAURICE [Electrometers for measuring variations in earth potential] 18,065/12; SIEMENS BROS. & CO. (*Siemens & Halske*) [Hot-wire instruments] 943/13.

**Storage Batteries:** WOOD [Accumulator lugs] 12,713/12.

**Switchgear, Fuses, and Fittings:** TURNER [Switches for multiple unit control] 13,740/12; B.T.H. and WALLACE [Switches] 15,776/12; SCHATNER [Electro-magnetic remote-control switches] 20,247/12; BURR [Oscillating spring contact for bells, &c.] 22,311/12; RAILING, STRACHAN and COATES [Time lags] 22,509/12; MAJORANA [Discharge apparatus] 23,024/12.

**Telephony and Telegraphy:** STERLING TELEPHONE (*Telephon Fabrick vorm J. Berliner*) [Combined intercommunication and party-line telephones] 6,580/12 and 7,593/13; KLEINSCHMIDT [Keyboard tape perforators] 8,960/12 and 1,267/13; BROWN [Telephony] 9,179/12; WILLIAMS [Automatic wireless alarm] 9,882/12; HILTZ [Printing telegraph receivers] 14,831/12; KNUDSEN [Telegraph apparatus] 15,591/12; IMRAY (*Cie Generale*

*Radiotelegraphique*) [Receivers for wireless] 28,070/12; FULLER [Antiseptic guards for telephone mouthpieces] 4,704/13.

**Traction:** TURNER [Electric tramway brakes] 15,023/12.

**Miscellaneous:** CLARKE and CHADBURN'S (SHIP) TELEG. [Direction tell-tale or indicator] 9,673/12; COOK [Keyboard controlled signals] 16,765/12; STEWART [Magnetic speedometers] 17,942/12; "CEDES" ELEC. TRACTION and CLIFFORD [Extensible ladders for fire-escapes] 20,244/12; GARNHAM [Egg tester] 22,603/12.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Dynamos and Motors:** ALLMÄNNA SVENSKA ELEK. AKTIEBOLAGET [A.C.] 7,776/13.

**Heating:** GEB. SIEMENS [Non-metallic elements] 7,932/13.

**Ignition:** BOSCH [Distributor] 5,532/13.

**Incandescent Lamps:** STEINMANN [Mercury vapour] 8,172/13.

**Instruments and Meters:** SIEMENS & HALSKE [Housing the recording strip of electrocardiographs] 7,846/13; [Photographically recording electrical measurements] 8,240/12.

**Switchgear, &c.:** BRUNN [Commutator switches] 2,295/13.

**Telephony and Telegraphy:** BLACKWELL [Reducing telephone disturbances] 2,508/13; KÄHLER [Telegraphy] 8,173/13.

**Miscellaneous:** CAMPBELL [Measuring capacities] 2,009/13; SIEMENS SCHUCKERT [Regenerating transformer oil] 8,130/13.

### Application for Amendment

20,277/04. **Manufacture of Drawn Tungsten Filaments.** C. D. ABEL (*Siemens & Halske*). Application has been made by Siemens Bros. & Co. for leave to amend this specification "for the purpose of narrowing the claims, more clearly defining the scope of the invention, and of removing matters which are superfluous." There are four claims to this specification. The first three cover the manufacture of drawn filaments of molybdenum, thorium, tungsten, zirconium, or alloys thereof, free from non-metals, by heating the metal or alloy in a vacuum or indifferent atmosphere by the passage of an electric current and then drawing the mass. It is proposed to delete molybdenum, thorium, and zirconium, and the claim for alloys, and to qualify tungsten by the word "drawn." In addition it is proposed to delete Claim 4 entirely. This is for manufacture from a compound of the metal with elements which are separated in a gaseous form on heating.

### Grant of Patent Allowed

26,184/11. **Oil and Electric Furnace.** V. STOBIE. The Comptroller has allowed the Grant of this Patent subject to Amendment.

### Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:—

9,882 of May 10th, 1899. **Train Lighting.** E. J. PRESTON and A. B. GILL (*J. Stone & Co.*). This specification covers some improvements in detail of the Stone system of train lighting. An electromagnetic switch on each coach is controlled by a switch in the guard's van. The lubrication of the bearings of the dynamo is controlled by electromagnets so that the oil supply is cut off when the dynamo is at rest. Where two batteries are used and are put in parallel by the short-circuiting of the resistance between them by the slowing down of the train, an increase of pressure, due to one battery being more highly charged, sometimes passes an increased current through the lamps. To obviate this the resistance is subdivided, only a portion being short-circuited.

The following are the more important Patents that have become void through non-payment of renewal fees.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** H. H. LAKE (*W. G. Clark, U.S.A.*) [Cable insulators] 1,395/07; R. B. RANSFORD (*W. A. Manson, South Africa*) [Insulated wire strainer] 980/08.

**Dynamos and Motors:** H. F. T. ERBEN [Adjusting effect of commutating poles] 5,866/07.

**Ignition:** A. F. WHITE [Magnet ignition] 1,091/06.

**Incandescent Lamps:** B. T.-H. (*A.E.G.*) [Filament supports] 1,196/07.

**Switchgear, Fuses, and Fittings:** T. S. PERKINS [Motor controllers with magnetic blow-outs and refractory shields] 13,860/00; C. A. PARK and C. L. MASON [Electro-magnetic switch for train lighting systems] 1,373/07.

**Traction:** R. and H. DUCKWORTH and D. KERR [Switches for the control of sectional conductor systems by the weight of the vehicle] 689/05.

**Miscellaneous:** W. FAIRWEATHER (*Arnold Magnetic Clutch Co., U.S.A.*) [Adjustable speed magnetic clutch] 1,349/04; J. C. BOUSFIELD (*P. Boll and R. Falkner, Australia*) [Sheep shearing machine] 906/08.

## TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

The attention of the Marconi Committee has at last been directed once more to wireless telegraphy. The members of the Committee themselves have been too much interested in speculations, rumours of speculations, and speculations as to the source of rumours, to devote themselves to expediting the establishment of the wireless telegraph system urgently needed for the British Empire; but the technical "Advisory" Committee, appointed to report on the merits of existing systems of wireless telegraphy, particularly with a view to their capacity for continuous communication over distances repaired by the "Imperial Chain," have now issued their report. It is a clear and well-written document, giving precisely the information required and the reasons which have actuated the members of the Technical Committee in coming to their decisions. It will be remembered that the Committee was formed of the following members:—Lord Parker of Waddington, Mr. Duddell, Dr. Glazebrook, Sir Alexander Kennedy, and Mr. Swinburne, with Mr. Rayner as Secretary.

Stated in the briefest possible terms, the finding is that the Marconi system is the only one which has proved itself up to the present to be suited for continuous and reliable signalling at useful speeds by day or night over distances of from 2,000 to 2,500 miles—the distances required by the "Imperial Wireless Chain." The other systems considered were the Telefunken, Poulsen, Goldschmidt and Galletti. In the last mentioned (which is little known) a series of spark gaps are employed, arranged to operate in a cycle, each discharge causing an immediate discharge in the next spark gap of the series, so that the resulting oscillations from the sequence of discharges may be regarded as practically continuous; no evidence was given, however, as to the practicability of this system, even over short distances, although a representative of the Galletti Company was one of the witnesses heard. As regards the two systems using continuous oscillations—the Poulsen and the Goldschmidt—the conclusion arrived at is practically the same as that given in Mr. Duddell's presidential address at the Institution of Electrical Engineers last year, namely, that the arc in the former and the generator in the latter will have to be constructed to give more power to the aerial if effective transmission is to be accomplished over the very long distances in question. The advantages of continuous over intermittent trains of waves in allowing more accurate tuning and greater selectivity is admitted, and the Committee actually express the opinion that ultimately high-frequency continuous oscillation generators will displace high-frequency generators dependent upon spark discharges which produce groups of oscillations, yet they point out that high power is the first essential for these long-distance transmissions, and in this respect the Marconi apparatus is undoubtedly superior to all others. It is working on a commercial scale over the 2,300 miles between Clifden and Glace Bay, and although the number of messages transmitted does not necessitate the regular use of duplex working, its possibility was satisfactorily demonstrated to the Committee. High-speed automatic transmission was also demonstrated to them: a speed of sixty five-letter words a minute was attained, and the Committee see no reason why this speed should not be greatly exceeded if necessary. The Marconi apparatus is described as follows:—

"The Marconi Company use at their Clifden station a high-frequency generator, in which condensers charged from the high-tension batteries are discharged by projections which are fixed on a rapidly rotating wheel, and which pass close to metal discs on each side of it. Each discharge produces a group of high-frequency oscillations in a primary circuit, according to the Company's usual practice. We observe that, for the purposes of the Imperial Chain, they proposed to charge the condensers from an alternator through a high-tension transformer, as is their practice elsewhere, including the long-

distance station at Coltano. This method is in our opinion preferable. . . . The communication is practically continuous, though there are, no doubt, periods when the signals become very weak, and even occasional periods when no signals can get through. Periods of this nature are due to natural conditions, and will be incident to the working of any system. During such periods communication can, in our opinion, be insured only by the use of great power in the aerial. We understand that for this reason, and having regard to the increased power required for high-speed transmission, the Marconi Company proposed to employ for the Imperial stations practically double the power now used at Clifden. Even so, we think there may be periods when communication is impracticable, especially in tropical regions, where atmospheric disturbances may be expected to cause more difficulty than over the Atlantic."

It is interesting to note that both the Marconi Co. and the Telefunken Co. are experimenting with continuous oscillation generators of their own. These are briefly described in the report:—

"The Marconi continuous high-frequency generator consists essentially of a rapidly rotating contact-maker in a direct-current circuit with special dispositions of other circuits to give continuous oscillations in the aerial. The Telefunken continuous high-frequency generator consists of an alternator constructed to give as high a fundamental frequency as may be convenient in the first instance, the frequency being doubled or quadrupled by a polarised transformer method."

The Committee point out that it is not within their province to report on the actual agreement made between the Post Office and the Marconi Co., but it is clear that they have in mind not only the terms of the agreement, but also its recent repudiation by the company. They point out that while the company has had unique experience in the sort of long-distance work required, including the erection of the stations and in organising the traffic and staff, yet the use of their system does not necessarily imply that they need be the contractors for its erection, and that in some respects it might be better for the Government itself to undertake this. The Post Office, they recommend, should reserve complete liberty of action and should not be pledged to the continuous use of any "system." Two of the stations, they think, should be allotted for experimental purposes and placed in charge of an engineer of high standing possessing special knowledge of the subject, with a highly-trained staff, and they think that the ultimate result would be that the Post Office stations would be "ultimately equipped with apparatus far more efficient than that now used in any so-called system, more especially as the Post Office will be able to combine, in spite of existing patent rights, apparatus or devices which, because of the existence of such rights, cannot now be combined by anyone else." Many engineering firms, the Committee states, are engaged in the design of high-frequency alternators for the generation of continuous waves, there is a wide field for experiment and development of receiving plant, and there is some evidence that the design of the aerial is in a transition stage. Approval is expressed of the Marconi Company's directive aerial; it has the advantage of not requiring very great height, its use with the separate receiving station comparatively close to the transmitting aerial makes duplex working practicable, and the Committee see no reason why this form of aerial should not be capable of use with any form of high-frequency generator.

A Bill has been introduced into the Canadian Parliament confirming a contract for a Poulsen wireless installation between Great Britain and Canada.

The line between Barfrough and Teheran was down on April 30th, and on the same day communication with India and Siam via Kanburi and Raheng failed.—The Moulmein-Raheng-Bangkok line was repaired on 2nd inst.—The lines to the Chihuahua and Sonora States of Mexico were also repaired, and on the 3rd inst. the Duala-Fernando-Po line was down.—An interruption on Siamese territory occurred to the Prompenh-Bangkok line.—On the 3rd inst. also there was delay to telegrams for offices between Loanda and Malange and Novo Redondo.—On the 5th inst. the Teheran-Barfrough communication and the line between Duala and Fernando-Po were repaired and were normal on 6th inst.

WHEN CORRESPONDING WITH ADVERTISERS. PLEASE MENTION "ELECTRICAL ENGINEERING."

## LOCAL NOTES

**Aberdeen: Electricity Accounts.**—In sanctioning a loan of £80,000 referred to in our Tenders Invited column, the Secretary for Scotland has suggested that there should be included among the appendices of the electricity accounts each year a tabulated statement setting forth the revenue of the undertaking for each year since the commencement, and the manner in which this revenue has been applied.

**Bexley: Electric Cooking Apparatus.**—The Electrical Engineer reports several applications for electric cookers on hire, and states that the cost of such apparatus and utensils is approximately £8 per set. The makers would guarantee and maintain the apparatus for four years, and assuming that the Local Government Board would sanction the borrowing of the necessary money and its repayment over a period of ten years, he anticipated that these cookers could be let on hire at the rate of 4s. per quarter. For hire-purchase the rate recommended is 15s. per quarter for three years, or 10s. per quarter for five years. The Council has adopted the Committee's recommendation to agree to this scheme, in addition to a rearrangement of the tariffs in order to include the rateable value system as an alternative. This latter is on the basis of 2s. 6d. in the £1 on the rateable value, plus 1½d. per unit.

**Dudley: Sale of Electricity Undertaking.**—The hitch in the arrangements for the transfer of the Council's electricity undertaking to a company, is on the question of the repayment of the outstanding loans. The arrangement in the agreement to which the Board of Trade has taken exception was that the Company should make the annual repayments in respect of the outstanding loans as they fell due. This, of course, left the ratepayers of Dudley responsible for the amounts still outstanding in the event of the Company for any reason failing to meet its liabilities. At the same time, similar arrangements have previously been sanctioned in connection with the acquisition of works by a company from a local authority, although not, we believe, in the case of electricity works. The Board of Trade requires that the Company should repay the whole of the loans immediately, but this would deprive the Company of the advantage of the lower rate of interest at which the Council has borrowed.

**Falkirk: Electricity Works Extensions.**—A new 600-kw. turbo-generator and condensing plant has just been put into operation, and a further 2½ miles of E.H.T. cable. A number of transformer sub-stations have also been installed in order to deal with increased power and lighting load. The cost of the extensions has been £6,000.

**Kilmarnock: Wiring Small Houses.**—The Council has approved a scheme for the wiring of dwelling houses up to a rental value of £20 free of cost, the charge for current to be at the rate of 5d. per unit for lighting purposes with a minimum of 25s. per annum. The approval of the Council is on the understanding that the scheme will be abandoned if it is not found to be profitable.

**West Ham: Electric Cooking Demonstrations.**—Mr. F. S. Grogan will give a series of electric cooking lectures and practical demonstrations at the Town Hall, Stratford, from May 20th to 23rd inclusive. The lectures will commence at 3.30 p.m. and 7 p.m. each day.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

## Generating Stations, Sub-Stations, Mains, &amp;c.

**Basingstoke.**—The Board of Trade has granted the Council an electric lighting provisional order, and it is anticipated that steps will be taken immediately to put it into force.

**Birmingham.**—The Electric Supply Committee have now issued their long anticipated report upon a new power station, in which they recommend the adoption of steam turbine plant, and an ultimate expenditure of £500,000, the capacity being then 100,000 kw. At the present rate of progress, the first section of the new power house of 15,000 kw. will be required for the winter of 1915-16. The Finance Committee have issued a report upon the scheme, and offer no objection to it on financial grounds.

**Bradford.**—An expenditure of £2,711 is contemplated on mains extensions.

**Bridlington.**—An expenditure of £3,000 is contemplated upon mains.

**Brighton.**—A new turbo-alternator is required.

**Derby.**—An inquiry has been held concerning a loan of £13,500 for electrical extensions.

One 750-kw. three-phase to single-phase motor-alternator. Borough Electrical Engineer, May 23rd. (See advertisement on another page.)

**Dundalk.**—A loan of £5,000 for electric lighting extensions has been inquired into.

**Dungarvan.**—Proposals for an electric lighting scheme are invited.

**Keighley.**—An inquiry has been held concerning a loan of £7,000 for a new turbo-alternator, switchgear, cables, &c.

**Kingstown.**—The Board of Trade have granted the Dublin Southern District Electric Supply Co. an electric lighting provisional order for Blackrock, Kingstown and Dalkey.

**London: Hackney.**—Land for two new sub-stations has been acquired.

**Lytham.**—The Board of Trade have granted the Lytham Council an Electric Lighting Order. It is stated to be the intention of the Council to commence the scheme immediately.

**Melbourne.**—Tenders are invited for 20,000-volt switchgear, and L.T. switchgear, for the power station and sub-stations in connection with the Melbourne railway electrification. The consulting engineers are Messrs. Merz & McLellan, 32 Victoria Street, S.W. Tenders to Agent General, Melbourne Place, W.C., by June 2nd.

**Plymouth.**—A new turbo-generator is to be installed at an estimated cost of £5,500, in addition to switchgear, cables, &c., costing £2,000.

**Rosyth.**—The Admiralty contemplate the erection of a large power station here.

**Salford.**—An inquiry was held last week concerning a proposal to borrow £35,900 for electrical extensions. There was no opposition. It is anticipated that £8,000 will be spent during the first twelve months on plant, and £4,000 on mains. A sum of £12,000 is also required in connection with bulk supply from the Lancashire Electric Power Co., details of which were given in our issues for February 13th, page 88, and February 20th, page 100.

**Shipley.**—A Local Government Board inquiry was held last week concerning a loan of £5,700 for electrical extensions.

**Worthing.**—The Borough Electrical Engineer has been instructed to prepare plans and estimates for additional plant.

## Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

**Aberdeen.**—Hospital and nursing home at Old Mill. Mr. J. A. Bell, the City Electrical Engineer, is advising.—New training centre buildings, St. Andrew Street. Architect, J. A. Allan, 25 Union Terrace.

**Bradford.**—Electric lighting of the Belle Vue Boys' Secondary School. City Architect, May 15th.

**Brighton.**—Municipal offices in Fisher Street.

**Dartford.**—Elementary school, Lower Road.

**Eastbourne.**—Sanatorium.

**Edinburgh.**—New buildings at St. George's High School for Girls, costing £25,000.

**Leeds.**—New school at Farnley.

**London: L.C.C.**—Electric lighting of the Lewisham Bridge and the Fairfield Road elementary schools. (See advertisement on another page.)

**Islington.**—A committee has been appointed to deal with the electric lighting of the workhouse.

**Ludlow.**—Isolation hospital.

**Manchester.**—New branch library.—Electric lighting of Withington workhouse. Architect, E. H. Overmann, 49 King Street, May 13th.

**Nottingham.**—Extensions to Council school at Trent Bridge. City Architect.

**Smethwick.**—Proposed school.

**Taunton.**—Proposed new town hall.

FOR  
STEAM JOINTS  
USE

JOHN HUDSON & CO.'S SUCCESSORS, Mansell St., London, E.

### TENDERS RECEIVED AND ACCEPTED

**Blackburn.**—A contract has been placed with the British Westinghouse Co. for a new turbo-generator.

**Coventry.**—The Corporation has accepted the tender of the Brush Electrical Engineering Co. for five double-deck trams with four-wheeled trucks.

**London: L.C.C.**—We refer on another page to the tenders for the two 8,000-kw. turbo-alternator sets for the Greenwich power house. The British Westinghouse Co. has received the contract.

**G.P.O.**—The contract with the General Electric Co. for the supply of Osram lamps has been extended for a further period of six months.

**Hampstead.**—As a result of tests carried out by Mr. H. H. Couzens, the Council has decided to adopt Mr. Haydn Harrison's design of fittings as used in Marylebone. In certain streets new posts are to be erected thirty yards apart, with the height of the light source such as to produce a satisfactory minimum illumination. Mr. Harrison has been instructed to proceed with the work immediately.

**Lewisham.**—The tender of Messrs. Weston & Son was recently accepted for the electric lighting of the infirmary, but this firm does not now wish to take up the contract at the price quoted. The Committee at its last meeting recommended the Board of Guardians to accept the tender of Messrs. Haycraft & Son at £759 10s., but after some discussion the matter has been referred back to the Committee for further consideration.

**Stepney.**—See page 263.

**Peterborough.**—The tender of W. T. Henley's Telegraph Works Co. has been accepted for cable at £566.

**Sheffield.**—The Corporation has accepted the tender of the Brush Electrical Engineering Co. for 25 double-deck trams with top covers and four-wheeled trucks.

**York.**—The tender of Callender's Cable & Construction Co. has been accepted for H.T. cables at £2,170. This was the lowest tender received.

### APPOINTMENTS AND PERSONAL NOTES

The following increases in salaries are recommended by the Glasgow Tramways Committee:—Mr. J. Dalrymple, General Manager, from £1,100 to £1,250 per annum; Mr. L. Mackinnon, Traffic Superintendent, from £600 to £625 per annum; Mr. J. Ferguson, Chief Engineer, from £600 to £625; Mr. E. T. Goslin, Electrical Engineer, from £550 to £660 per annum.

Mr. H. F. Street, Electrical Engineer and Tramways Manager to the Southampton Corporation, has been permitted to relinquish the Tramways Managership owing to the enormous increase in the size of the electricity undertaking during recent years. He will in future give his whole time to the electricity undertaking at his present salary.

Mr. A. W. Barham, Chief Assistant Engineer to the Watford Urban District Council, has been appointed Chief Electrical Engineer in succession to Mr. F. W. Purse, recently appointed to Carlisle.

Mr. G. F. Naylor, Assistant Electrical Engineer, has been appointed Chief Electrical Engineer and Tramways Manager by the Nelson Corporation in succession to the late Mr. D. Helme.

The salary of Mr. A. G. Cooper, Borough Electrical Engineer at Colne, has been increased from £300 to £325 per annum.

Mr. B. Andrews has been appointed Manager of the Southport Tramways at a salary of £200 per annum.

Mr. W. E. Bradshaw, of the Charing Cross, West End and City Electric Supply Co., Ltd., has been appointed to the position of Mains Superintendent at Islington, recently rendered vacant by the resignation of Mr. T. A. G. Margary.

Mr. H. W. Leonard, of the Publicity Department of the General Electric Co., was given a first prize at a fancy dress carnival at Birmingham recently for a costume representing Aladdin and the wonderful (Osram) lamp.

An engineering representative for power business is required in the Sales Department of the Bristol Electricity Department. (See advertisement on another page.)

A chief assistant electrical engineer is required by the Watford Council. Commencing salary, £150 per annum.

### MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. George Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £72 5s. to £72 15s. (last week, £72 to £72 10s.).

**Companies Struck off Register.**—The names of the following have been struck off the register of joint stock companies:—Electrical and Mechanical Exhibition; Electric Coin Freed Meter Dimming Syndicate; Hirst Magneto Co.; Illuminating Engineering Co.; S.P. (Suchostawer Patents) Syndicate; Schreiber Electric Battery Co., and the Vulcan Dynamo and Motor Co.

**Agency.**—Messrs. Dorman & Smith, switchgear and fittings manufacturers, of Ordsal Electrical Works, Manchester, have made arrangements to be represented in Scotland by Mr. David Alexander, of 43 Mains Street, Waterloo Street, Glasgow. Telephones: Central 4394, Argyle 587; telegrams, "Ohmie, Glasgow."

**Bohemian Concert.**—The space factor of the large hall devoted to the annual Bohemian Concert of the Football Section of the General Electric Company's Athletic Club, in the Talbot Restaurant, on Saturday evening last, must have been extremely high. The stewards were given a very busy time endeavouring to find room for the visitors to the number of about 300 who came to enjoy the long programme, every item of which was thoroughly appreciated. During the evening the Chairman, Mr. L. Byng, announced that the G.E.C. Cricket Club had that day been successful in their first match this season. The "Davis Cup" (competed for by the Electrical Trade) was then presented to the G.E.C. Football Club by the donor, Mr. S. Davis, who also gave medals to the members of the eleven.

### COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

**Nairobi Electric Power & Lighting Co.**—At the meeting yesterday a report was submitted recording a net profit of £2,642 for 1912. The construction of the further stations on the Ruera River has been delayed in consequence of negotiations with the Government.

**British Westinghouse Co.**—The report and balance-sheet for 1912 shows a gross profit of £157,871. A sum of £43,449 is set aside for depreciation, in addition to £6,300 for redemption of prior lien debentures. After deducting debenture and mortgage interest, &c., there is a net profit of £41,074, compared with £20,708 last year. With the balance brought forward, there is a credit of £66,889, which it is proposed shall be carried forward. Reference is made in the report to the successful appeal to the House of Lords with regard to the Lot's Road turbines, and the fact is recorded that the orders received during 1913 show an increase over those of the corresponding period of 1912.

At the annual meeting on Monday, the Chairman emphasised the improving position of the Company, not only as the result of last year's trading, but from the fact that in the first three months of this year they had done very well indeed. With regard to the arbitration concerning the Lot's Road turbines, no date has yet been fixed by the arbitrator to make his award, and until this was given nothing could be said with regard to a reduction of capital. A shareholder asked as to the possibility of a combination of electrical manufacturers in this country with a view to reducing the present excessive competition, but the Chairman pointed out the difficulty of this, and remarked that for years the directors had been trying to bring about an arrangement to avoid the cutting of prices.

**Derbyshire & Notts Electric Power Co.**—At the annual meeting last week, Mr. A. R. Holland, the Chairman, stated that by the introduction of new capital the Company's outstanding liabilities have been liquidated, and sufficient has been subscribed for the proper development of the Company's power area. A contract has been entered into amounting to £89,750 for additional plant and machinery, including sixteen miles of new cables and the equipment of seven sub-stations, and already a 1,000-kw. turbo-generator set has been supplied, whilst a further 2,500-kw. set is on order. A contract has been entered into for supplying a new tramway running from Ripley to Nottingham. The accounts for the half-year to December 31st show a balance of £739, which is carried forward.

## SUMMARY

THE question of textile mill driving was dealt with in a group of papers recently published in the Journal of the Textile Institute. The relative merits of steam turbines, reciprocating steam engines, gas engines, and Diesel engines were discussed, and another paper dealt with the special requirements of different classes of textile machinery as regards driving, and showed how these could be met by electrical methods more perfectly than in any other way. The advantages of individual drive were particularly insisted upon. (Page 271.)

A CORRESPONDENT calls attention to the similarity of Prof. Dussaud's "cold light" system to certain early experiments with carbon lamps, and is very sceptical as to its ultimate success. (Page 271.)

AN interesting lecture on the electrical state of the atmosphere and methods of ascertaining it was given by Prof. E. Rutherford at a recent meeting of the Manchester Local Section of the Institution of Electrical Engineers. (Page 272.)

MR. A. E. HADLEY's Paper on the electric power supply system to the Rand mines has been further discussed by the Glasgow Local Section of the Institution of Electrical Engineers. (Page 272.)

A NEW electric cooking outfit of low current consumption is illustrated on page 273.

RESULTS of some experiments by Dr. Michie, described in a Paper read recently before the Newcastle Local Section of the Institution of Electrical Engineers, attribute the formation of deposit in transformer oil to partial oxidation. (Page 273.)

SOME designs of switchgear which can be connected up direct to armoured cable without the use of "tails" are illustrated. (Page 274.)

PROBLEMS connected with three-phase supply and with the testing of mining apparatus are propounded in our Questions and Answers Columns. (Page 275.)

SOME interesting electrical instruments, including recorders, portable instruments, pyrometers, and insulation and resistance testing sets, are referred to. (Page 275.)

AN enclosed switch panel, designed with special interlocking arrangements to render it mistake-proof, is described. (Page 276.)

THE premiums and scholarships awarded by the Council of the Institution of Electrical Engineers are announced. The "Institution" Premium has been awarded to Mr. A. E. Hadley for his Paper on "Power Supply on the Rand." (Page 277.)

A NEW automatic telephone exchange system, the Betulander, is being introduced by the Marconi Co. It possesses features different from other automatic systems, and these are described and illustrated.—Mr. Marconi has at last been called before the House of Commons Committee, which is inquiring into the Imperial wireless telegraph scheme, and has corrected a number of mis-statements which have been made by previous witnesses. He maintains, among other things, that the Admiralty is using the Marconi system pure and simple, in spite of their claim that they have improved it. (Page 277.)

THE Specifications published by the Patent Office on Thursday last include one for submarine cables loaded on the Pupin system, and four important ones relating to the manufacture of tungsten lamps. Our "Patent Record" also contains notes on some Opposition and Amendment cases. (Page 278.)

SIX electric vehicles took part in the parade of commercial motor vehicles organised by the Commercial Motor Users' Association on Whit Monday—Large sums are being transferred to relief of rates by the Leeds and Belfast Tramway Departments. (Page 279.)

AN important scheme of street electric lighting is to be carried out in Manchester.—A report on street lighting by electricity is to be presented to the Bombay Corporation.—The Birmingham Gas Department claim that better results would be obtained with gas engines than with steam turbines for the new electric power

station.—Broughty Ferry is to be incorporated with Dundee.—The coal bill for next year at Nottingham is estimated at £8,000 more than in 1912 owing to increased prices.—An economy of £2 10s. per night in the fuel bill is reported at Bray through the use of Diesel engines. (Page 279.)

THE Leeds Corporation contemplate an expenditure of £168,000 on their electricity undertaking.—Switchgear instruments are required by the Melbourne Corporation; mains and services at Belfast; and switchgear at Lyttelton (N.Z.).—Generating plant is required for a Bulgarian coal mine; high and low tension cables by the London County Council; and loans of £33,400 and £10,000 are contemplated by the Rhondda and Wellington (South Africa) Councils respectively.—Wireless telegraph stations are required in Spain and Indo-China, and an electric lighting scheme at a cost of £18,000 is being prepared for Ilkley. (Page 281.)

A VERY satisfactory year's working is reported by Callender's Cable & Construction Co., a dividend of 10 per cent. being declared for the year, together with a bonus of 5s. per share.—Messrs. Willans & Robinson also show improved results for 1912, there being a small profit of £154, and the Directors' report states that a greater volume of work is being dealt with, and that prices are improving.—A 10 per cent. dividend is declared by the Chloride Electrical Storage Co. (Page 282.)

**Strike of Electrical Wiremen in Leicester.**—In order to arrive at a settlement of the wages dispute between the employers and the electrical wiremen in Leicester, a conference was held on Thursday at the Town Hall, with the result that both sides have agreed to submit a basis of settlement to their respective associations.

## ARRANGEMENTS FOR THE WEEK

MONDAY, MAY 19TH.

*Institution of Electrical Engineers: Newcastle Students' Section.*  
7.30 p.m. Annual General Meeting at Armstrong College.

TUESDAY, MAY 20TH, TO SATURDAY, MAY 24TH.

*Institution of Electrical Engineers.*

Meeting in Paris.

FRIDAY, MAY 23RD.

*Royal Institution.*

9 p.m. Evening Discourse: "The Secret of the Permanent Magnet," by Prof. S. P. Thompson, F.R.S.

### The London Electrical Engineers.

(To-day) THURSDAY, MAY 15TH. *C. Company.*—Infantry Drill, 7 to 9 p.m. Technical Instruction for all Members on the Sixth Rate and for all Candidates for Higher Rating, 7 to 9 p.m. Musketry Instruction, 9 to 10 p.m.

FRIDAY, MAY 16TH. *D. Company.*—As for Thursday, 15th.

SATURDAY, MAY 17TH.—Annual Musketry at Purfleet. Headquarters open from 10 a.m. till noon.

MONDAY, MAY 19TH. *A. Company.*—Infantry Drill, 7 to 9 p.m. Technical Instruction for all Members on the Sixth Rate and for all Candidates for Higher Rating, 7 to 9 p.m. Musketry Instruction, 9 to 10 p.m.

TUESDAY, MAY 20TH. *B. Company.*—As for *A. Company*, May 19th.

WEDNESDAY, MAY 21ST. *All Companies.*—Annual Musketry at Purfleet Rifle Ranges. Railway tickets will be sent to those notifying Headquarters of their intention to attend.

THURSDAY, MAY 22ND. *C. Company.*—As for *A. Company*, May 19th.

FRIDAY, MAY 23RD. *D. Company.*—As for *A. Company*, May 19th.

SATURDAY, MAY 24TH. Headquarters will be open from 10 a.m. till noon.

**The National Physical Laboratory.**—The annual report for the year 1912 has now been issued, but the annual inspection, instead of being held as usual in March, has been postponed till June 26th, when Mr. A. J. Balfour will open the new buildings recently erected. These buildings complete a scheme initiated in 1909 to provide laboratories in metallurgy and optics with administrative offices, and their cost is being defrayed partly from a generous gift of the late Sir Julius Wernher, partly from a Treasury grant, and from other sources. Additional funds are still needed to provide adequate equipment. The block of buildings for optics and administration is now nearly complete, and it is to open these that Mr. Balfour has promised to be present on June 26th.

"GUARANTEED COAL."

(See page 263 of our last issue.)

CALORIMETRICAL ASSISTANT (from the laboratory upstairs): Is this semi-bituminous pseudo-anthracite washed peas with a calorific value of 13,350 British Thermal Units?

STOKER: No, sir; it's COAL!

## ELECTRIC DRIVING IN TEXTILE FACTORIES

IN the last number of the *Textile Institute Journal*, which contains the proceedings of the Congress held in September last at Hawick, a discussion on a group of papers on power in textile mills is reported. In an introduction to the papers reference is made to the joint committee of the Yorkshire Local Section of the Institution of Electrical Engineers and the Textile Institute, which was formed some time back to investigate the claims of different methods of driving textile factories. It will be remembered that this committee was disbanded before very much useful work had been done, as the Textile Institute, on going into the matter, considered it desirable that the rival systems should be reported on, independently of the great engineering institutions, and finally a committee was formed composed exclusively of members of the Textile Institute. The papers read at the Congress served as a general introduction to more detailed work of the committee, who had up to that time only settled certain standard nomenclature and bases for estimating to assist in comparing the data obtained.

The first Paper, by Mr. G. B. Storie, was on steam power in textile mills, and dealt in a large measure with steam turbines, which are now adopted by some of the larger concerns in this country for driving their mills. A list of forty-two mills with steam turbine installations was given in the Paper, all in conjunction with electric drive, and all except two were examples of alternating-current systems. No case of mechanical transmission from turbine drive was mentioned, and incidentally the Paper was striking evidence of the way that electric transmission had rendered the advantages of the turbine available to textile mills. The author praised particularly the steadier speed of the turbine over that of the reciprocating engine, a feature of special importance in textile work, whatever method of transmission is adopted, and the freedom of the exhaust steam from oil, which rendered it suitable for heating work throughout the mill, instead of the live steam through reducing valves. Other advantages of the steam turbine and the possibilities opened up by exhaust and mixed pressure turbines were gone into.

The second Paper, by Mr. T. R. Wollaston, was on gas power in textile mills, and scarcely touched the question of electrical driving beyond remarking that everything which the author had to say in favour of gas power for mechanical driving in textile mills, applied with added import in regard to the generation of electrical energy, whether at the mill or at the central station supplying the mill. Another Paper, by Mr. F. Carter, put forward the claims of the Diesel engine for mill driving. These engines seem to be used to a considerable extent for the purpose in India, and a list of twenty Diesel engine-driven mills, of which the four largest employ electrical transmission, was given.

Electric driving *per se* was taken up in the last Paper of the group, by Mr. J. F. Crowley. At the outset he referred to the rapid strides that are being made in the application of electric driving. Eight years ago the horse-power of the motors thus employed in Great Britain was a few hundreds, practically all at one mill. Four years later it had increased to 28,000, and to-day, he said, the joint textile load of three power supply companies would practically total this figure, which was less than the advertised sales of textile motors of any one of several electrical manufacturing companies. He said that with modern mills the case for electric driving did not rest mainly on a saving in transmission losses (although when there was any complication in the drive the saving was considerable), but on the steadiness of the drive, resulting in higher maintained speeds, increased production, improved quality of material and certain specific advantages in individual drive, resulting in still greater production and improvement in quality. So far as speed variation, the mule was the worst offender, and tachograph records had shown variations of 25 per cent. in the speed with mechanical drive, corresponding to 19 per cent. for D.-C. motor drive, or 6 per cent. for A.-C. motor drive. The very unequal power curve of the mule affected the running of every machine in any way connected with the shafting. On electric drive, mules may be group or individually driven, an important principle to be borne in mind being that, as far as possible, constant speed should be maintained during the "draw" on the actual spinning portion of the cycle. A given variation in speed where mules are group driven is liable to be far more serious than a variation of similar range with individually-driven mules. With individual drive, the speed fluctuations would naturally result from the variation in load of the mule itself, and would therefore follow the cycle of operations of the mule. With individual drive not only is less power required, but production is increased by at least 5 per cent. over that of

the same machines driven in groups. For mule driving the motor should have good efficiency over a wide range of load and high overload capacity. It is, however, in the case of ring spinning and doubling frames that electric driving has scored the most conspicuous success. As is well known, when a ring frame is driven at constant speed, the yarn is subjected to varying tension, and as the speed at which the machine can be run is determined by the maximum tension the yarn will stand, it must be such as to prevent this tension being exceeded at any moment; consequently, with a constant speed, considerable loss in production occurs. The only satisfactory solution to this, writes Mr. Crowley, so far has been the electrical one, which gives not only a low speed during the forming of the base of the cop, but also an automatic variation of the speed during the cyclic movement of the ring rail. For this purpose single and three-phase commutator motors of special design have been developed. Tests are quoted showing increases in output due to this method of driving, of 15 and in one case of 18 per cent. In a similar way the speed at which looms can be driven can be increased by the adoption of individual motor drive, and the great variations in speeds experienced with mechanical drive at different distance from the engine avoided. Tests show increases in speed of the machines of 9 per cent., without any increase in breakages, with improvement in the material and improvement in the load factor, bringing up the increase of production to over 15 per cent. Somewhat more power was, of course, required to drive the looms, but in weaving the power costs were but a small percentage of the whole, so that the increase had little effect on the cost of the product. The latter part of the Paper dealt with the choice of generating plant, transformers and switchgear, and a few words were added on outside power supply, which, when available, is often economical. For the usual cotton mill load factor of 25 to 29 per cent. can be purchased at about 0.5d. per unit, and in one area some manufacturers actually obtain current at 0.3d. per unit.

The discussion turned largely on the prime mover side of the question, but there was some criticism of the claims of electric driving. In one case it was argued that for the money spent on electrical equipment extra looms might be bought and an equal increase in output obtained. Some speakers thought that the variations in speed with mechanical drive had been exaggerated, and the defenders of mechanical transmission called attention to the excellent efficiencies obtained by modern ball-bearings and chain drive. Confirmatory testimony was also given by those who had experience of the excellent results obtained by electrical driving.

## CORRESPONDENCE

## "COLD LIGHT."

To the Editor of ELECTRICAL ENGINEERING.

SIR,—The report in this week's issue of ELECTRICAL ENGINEERING of Prof. Dussaud's proposal for furnishing light by means of incandescent lamps, to which current will be delivered intermittently, is a revival of a very old thing, which was proposed in the very early days of the carbon filament lamp. Immediately it was seen, in the early days of the 50-volt lamp, that the filament preserved its condition of incandescence for a certain period after the current was switched off, and that it took a certain time after the current was switched on to raise it to incandescence, many minds were turned to the possibility of saving current. I may confess to have dabbled a bit in the matter myself; but what I found was, and I think what earlier experimenters found was, that there was nothing gained. If you eliminated the flicker in the lamp, you lost in other directions, in the apparatus required to cause the current to be delivered intermittently; so that you had an additional apparatus, costing a certain amount, and requiring looking after, without any equivalent advantage.

The metallic filament lamp has the advantage that its resistance increases with the temperature, and *vice versa*; but I should be strongly inclined to think that our experience of 30 years ago would be repeated in Prof. Dussaud's apparatus.

Bath, May 8th, 1913.

SYDNEY F. WALKER.

**Obituary.**—Many of our readers will be sorry to hear of the bereavement of Mr. L. M. Waterhouse, Managing Director and Engineer to Simplex Conduits, Ltd., who has just lost his wife. Mrs. Waterhouse, who died on Wednesday of last week after a short illness complicated by a chill, was a sister of Mr. A. W. Robinson, Manager of the Company's Publicity Department.

## SMALL INDUCTION MOTORS FOR ALL CLASSES OF WORKSHOP DRIVING.

PROMPT DELIVERY IN SIZES FROM  
½ TO 10 H.P. AT ALL THE USUAL  
SPEEDS AND PRESSURES.

OPEN, PROTECTED & ENCLOSED TYPES.

HIGHEST GRADE MATERIAL and  
WORKMANSHIP.

CAXTON HOUSE, WESTMINSTER, LONDON, S.W.

And at MANCHESTER, GLASGOW,  
and NEWCASTLE.

### THE ELECTRICAL STATE OF THE ATMOSPHERE

AFTER the Annual General Meeting of the Manchester Local Section of the Institution of Electrical Engineers on April 8th, Prof. E. Rutherford, F.R.S., gave an interesting lecture on the above subject, illustrated by experiments. Interest in the electrical state of the atmosphere might be said to date from Franklin's experiments in 1749, which resulted in the introduction of the lightning rod. Some time later it was first observed that the potential of air to earth was usually positive, while the potential gradient is about 100 volts per metre.

Passing on to methods employed for measuring the potential of a point in space, Prof. Rutherford gave a demonstration of the use of the Kelvin water-dropper and electrometer, and afterwards substituted for the water-dropper a radio-active substance emanating  $\alpha$ -rays. This gave much quicker results. Ionium was the best substance to use, as it emitted only the  $\alpha$ -rays, and not the  $\beta$ - and  $\gamma$ -rays. It had been used very successfully by Simpson in the *Terra Nova* expedition. The proximity of buildings might modify very considerably the results obtained when determining the potential of the air at a given place, and the results should be checked by determinations in the open. Simpson made use of a horizontal insulated wire carrying the tube of ionium and having one end connected to the electroscopes in his determinations. The potential of a given place has been found to vary during the year, the minimum value being found in midsummer and the maximum about January. There was also a diurnal variation, and from some results taken at Kew it was found that the minimum occurs there about 4 a.m. and 2 p.m., the maximum being reached at about 9 a.m. and 9 p.m.

In some places, however, no variation has been found. For instance, in the Arctic Simpson found no variation, nor is any found on the Eiffel Tower or on mountain peaks.

It is found that the potential gradient decreases with altitude, as the following figures show:—

Height: Feet ...	0	824	1060	2080	2820	3136	4085
Potential Gradient:							
Volts per metre	150	37	43	21	20	19	13

Although pure air is a perfect insulator, the ordinary atmosphere has a marked conductivity. This is due to the presence of ions in it, some of which were small and moved swiftly, and some large and moved very slowly. Prof. Rutherford demonstrated the presence of the ions by experiments. Unless the ions were being continuously produced and maintained by some agency, it is probable that they would disappear completely in a very few hours, as 8 per cent. of positive electrification dissipated in one hour. There were, however, many agencies at work keeping up the supply of ions. The Bunsen flame, for instance, was highly ionised. The origin of ionisation was due, in Prof. Rutherford's opinion, to radio-active material.

In experiments it usually appeared that the positive ions were apparently in excess of the negative ions, but as it can be shown that an excess of only 1 per cent. of positive ions over negatives would account for the whole phenomena of terrestrial electricity, it is clear the apparent excess of 20 per cent. is due to errors and inaccuracies in the apparatus employed in the experiments.

If the ions were set up by emanations from the earth it might be expected that the ionisation over the sea would be less than over the land, but in the North Atlantic it was found to be about as much as on the land. Simpson, however, on the Antarctic expedition found that as the land was passed and its influence decreased, the drop in ionisation was very pronounced.

Prof. Wilson, of Cambridge, had calculated that the total vertical current passing from the atmosphere to the earth over its whole surface was about 1,000 amperes. It was obvious that there should be a return current of equal value passing back to the air somewhere, but at present there was no acceptable explanation to offer as to how this return current goes back.

### POWER SUPPLY ON THE RAND

THE Paper by Mr. A. E. Hadley, describing the power system of the Victoria Falls and Transvaal Power Co. and the Rand Mines Power Supply Co., read in London on March 13th (see *ELECTRICAL ENGINEERING*, March 20th, p. 159), was further discussed by the Glasgow Local Section of the Institution of Electrical Engineers on April 15th.

Mr. W. McWHIRTER referred to the use of earth guard-wires, but said that although they serve as a great protection against lightning, they do not protect from static discharges. He advocated a high resistance between the line and earth as the only solution to the periodical breakdowns.

Mr. BUNTON (Bruce, Peebles and Co.), commenting on the load dispatchers, remarked that it is a particularly interesting thing to see in a large transmission scheme the method of controlling the whole of the large transforming station so that the attendant knows exactly when all the intercommunicating switches are open or closed.

Mr. SAM MAVOR (Mavor and Coulson) was particularly interested in the portion of the Paper dealing with compressed air.

Mr. W. L. SPENCE said that the figures with regard to efficiency in air distribution were open to suspicion, but if correct the scheme of distribution justified itself.

Mr. MACLEOD (Clyde Valley Electric Power Co.) referred to the boiler-house arrangements and the dependence on fans to provide induced draught. He favoured spare motors and the adoption of direct current to provide a more flexible arrangement. He condemned the use of overhead lead-covered wires for operating the balancing protecting gear, and the possibility of the telephone wires being energised in the event of a series transformer failing.

Mr. ROBERTSON (Clyde Valley Electric Power Co.) asked the comparative loss per mile on an 80,000-volt distribution and a 10,000-volt distribution.

Mr. D. A. STARR (Clyde Valley Electric Power Co.) said that the system of control described in the Paper was very similar to that used in Newcastle and the Clyde Valley Co.

**City and Guilds (Engineering) College.**—Our attention has been drawn to the fact that in the description of the traction plant of this Institute appearing in *ELECTRICAL ENGINEERING*, May 1st, p. 247, the equivalent tramcar inertia obtainable by the adjustable flywheels was given as 5, 10, or 15 tons, whereas the actual values are 10, 15, or 20 tons.

**The Junior Institution of Engineers.**—A week-end excursion, July 4th to 7th, has been arranged by this Institution to Brussels for the purpose of visiting the Ghent Exhibition. The party will leave London on Friday, July 4th, and visit the Exhibition on the Saturday. For the Sunday excursions will be arranged to Dinant, the Valley of the Meuse, the Field of Waterloo, or Antwerp, and on the Monday, places of interest in Brussels will be visited, the party returning to London in the evening.

## A NEW FORM OF ELECTRIC COOKER

A novel form of electric cooker, which, on account of its low initial cost and small current consumption, is particularly suitable for small households, has been designed by Simplex Conduits, Ltd. (116 Charing Cross Road, W.C.). The "Plexsim" cooker takes 600 watts as a maximum, but

FIG. 1.—PLEXSIM COOKER, OPEN.

facilities provided for regulation, and the manner in which the heat is retained by means of the special mode of construction adopted, result in the average demand of the oven being considerably less. With the assistance of one or two auxiliary hot-plates, or self-contained utensils, it will carry

FIG. 2.—PLEXSIM COOKER, CLOSED.

out all the functions of the ordinary cast-iron cooker of the gas-stove type. It is calculated that such a complete equipment should be sold within the region of £5, and that the maximum demand of the complete set would not exceed 2,000 watts. Such a set is now in course of preparation.

FIG. 3.—PLEXSIM COOKER, DISMANTLED FOR CLEANING.

The "Plexsim" cooker which is now being introduced has undergone exhaustive and severe tests under practical working conditions in the Company's experimental kitchen in Birmingham.

The general construction of the apparatus is well shown in the three figures. The way in which the Dutch oven-shaped cover containing the heating elements when swung away from the heat-rack retains its hot air, owing to the presence of the screen, E, avoids heat losses when examining the food being cooked, and the shape of the oven ensures very even distribution of heat. The cooking temperature is reached in five minutes, and a good roasting action is given by the heating elements, which are run to incandescence. As shown in Fig. 3, the apparatus is easily dismantled for cleaning by withdrawing the pins, B.

## TRANSFORMER OIL

A PAPER by Dr. Michie entitled, "The Formation of Deposits in Oil-cooled Transformers," was read before the Newcastle Local Section of the Institution of Electrical Engineers recently. The Paper dealt with some of the chemical changes which occur in transformer oils during use, and more particularly with the formation of the solid matter which deposits on the windings and other parts of transformers. These deposits vary in appearance from pale yellow soft sludges to dark brown or black hard masses, and their presence materially affects the circulation of the oil and leads to overheating of the windings. Various theories have been offered to explain their formation. They have been supposed to be due to the deposition of solid paraffins from the oil, to the separation of suspended solid particles under the influence of electrical stresses, to the disintegrating action of the oil on the varnishes and other materials used on the windings, and to the polymerisation of the oil under the action of heat. Experiments had, however, shown that electrical stress alone did not produce any deposit. In some cases, chemical analysis of deposits revealed traces of lead or manganese, which substances are used in the varnish on the coils, but the quantity of deposit is too great to be obtained from the varnish alone, and appears to be due to oxidation of the oil, a theory confirmed by experiments where oils were subjected to currents of air at elevated temperatures. Different oils behaved very differently. The presence of ozone in the air greatly increases the rate of sludge formation, and by using ozonised air a heavy deposit was obtained from an oil in a comparatively short time at 90° C. The rate of sludge formation is accelerated by the presence of certain metals, notably copper. The quantity of sludge which separated out in the oxidation process is largely dependent on the degree of refinement of the oil. As a general rule the more an oil is refined the more stable it becomes towards oxidising agents. Although several transformer oils are on the market, which when subjected to the oxidation test give no deposit after 45 hours, no oil has been met with which did not give rise to deposit after prolonged treatment. If the formation of deposit is to be minimised, the following conditions should be avoided: overheating, undue access of air to the oil, conditions likely to give rise to the formation of ozone, and contact of the oil with clean surfaces of copper, iron, and lead.

Mr. P. V. HUNTER (the Newcastle Electric Supply Co.) pointed out that it was most difficult to ascertain whether a transformer was sludging without lifting it out of its case. The Newcastle Supply Co. was one of the first to experience trouble due to sludging, and he thought that this was probably due to the fact that they used transformers which depended upon ducts for rapid cooling, whereas the earlier transformers had no ducts. He asked if cotton covering had any effect on preventing sludging, as he had recently come across a case of a larger low-tension furnace transformer which sludged very rapidly, and he could only put this down to the large amount of exposed copper.

Mr. MOORHEAD asked if an oil which had sludged and then been filtered had its flash point reduced, and also whether a filtered oil would sludge in the same proportion as previously.

Mr. SCHUL (A. Reyrolle & Co.) asked if it was possible that the minute traces of acid and alkali left in oils after purification would have any effect upon the contact surfaces of oil switches. It was an undoubted fact that small quantities of sulphur, such as was used for fixing insulators and other parts in oil switches, dissolved in oil and gave rise to various troubles.

Mr. G. STONEY said that the Paper explained the black deposits frequently found in turbine bearings.

Mr. W. C. MOUNTAIN (in the chair) said that sludging seemed to be largely a question of price, and, so far as it could be seen, it could also be prevented by rating transformers within reasonable limits.

Messrs. Wilson, Vernier, and F. O. Hunt also spoke.

Dr. MICHIE (in reply) said that cotton covering evidently had the effect of minimising sludging. As a rule oil which had been filtered was liable to form further quantities of sludge.

## CATALOGUES, PAMPHLETS, &c., RECEIVED

**TURBO-ALTERNATORS.**—Bruce, Peebles & Co., Ltd., have just issued a specification sheet dealing with their standard turbo-alternators. On the front page is given an illustration of the enclosed type of machine, which is the standard arrangement for all, excepting the two smallest sizes, which are made of the open type. Very full information is given with regard to winding and insulation, brush gear, ventilation, &c., and, although a short reference is made to the exciter, it will be noted that a full specification regarding the exciters is to be found on a separate sheet.

**CINEMATOGRAPH GENERATING SETS.**—Some convenient self-contained petrol-driven portable generating sets for cinematographs are dealt with in an illustrated list from Fyfe, Wilson & Co. (155A St. Vincent Street, Glasgow). The set complete with switchboard is mounted on a four-wheel hand-truck, and is made in several sizes. Stationary sets are also listed.

**LAMPS AND LAMP HOLDERS.**—New lists from the Electrical Co., Ltd. (122-124 Charing Cross Road, W.C.) deal respectively with radiator lamps, and "Goliath" screw holders for high candle-power lamps.

*Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."*

**WASHING MACHINES.**—Leaflets and pamphlets from Seear, Page and Co. (16 and 17 Devonshire Square, E.C.) describe the "Maytag" electrical washer. The wringer is adapted to swing into any position, and provision is made for using the motor to drive other domestic appliances.

**DRY CELLS, INSULATING TAPE, &c.**—A booklet from Turners & Manville, Ltd., Hopetoun House, Lloyd's Avenue, E.C.) deals with dry cells of the "J. M." pattern, adhesive insulating tapes, asbestos listing and fireproof tape, "Niagrite" fireproof tape, and other specialities supplied by the firm.

**GOODS TRANSPORTATION.**—The enterprise of the Great Central Railway Company, which has shown itself in divers ways, has just resulted in the publication of a well-bound, copiously illustrated book of about 270 pages, entitled "Per Rail." The subjects dealt with include descriptions of the Company's warehouses, siding and dock accommodation in the various important towns in the United Kingdom, together with notes on the productions of these towns and other interesting matter. A description of the recently opened deep-water dock at Immingham is also given, and the magnitude and convenience of this is brought home to the reader by a large coloured bird's-eye view. In addition there are two useful folding maps, one showing rail communication between different towns, and the other by a convenient colour scheme shows at a glance the present position of coal-bearing strata and iron ore, &c., in the Midlands and North of this country. A list of receiving offices and stations between which the Great Central Railway Company carries merchandise traffic terminates the volume, which will be supplied to any trader on application to the Publicity Department (216 Marylebone Road, N.W.).

## SWITCHGEAR WITHOUT TAILS

IT is a pity that so many installations are spoilt by an untidy, and sometimes unsafe, conglomeration of cable connections round about the switchgear. There is no need for it if proper thought and attention be given to the method of leading the connections in and out of the switches. So often it has been the practice to procure switches without a thought about the fact that these have to join on to a multi-core cable, and so when the ends of the cable are brought near to the switch terminals a box is put on to the cable and a set of tails join the box to the switch. Then, again, when the switch has to be joined up to the motor, how often do we find straggling single leads where a well protected and neat armoured job might have been adopted with very little extra expense? Messrs. A. Reyrolle & Co. (Hebburn-on-Tyne) have for years made the design of dividing boxes a study in a line with the design of switches and switchgear, and they have shown how neat and how complete an armoured system can be made. For instance, Fig. 1 shows a 3,000-volt three-phase switch which was to be placed direct in a cable run, and the dividing boxes are accordingly fixed in a horizontal position. The space occupied by this arrangement is much smaller than would be the case if tails were used, and, moreover, the job is solid and the live conductors are inaccessible. In another case the leads come in and out from overhead (Fig. 2). In this instance a coned gland is used to pinch on to the armouring of the cable. Innumerable examples might be given to demonstrate the

useful combination of the study of the switchgear terminal and the cable end, and if this is thought out carefully in

FIG. 1.—OIL SWITCH WITH HORIZONTAL ARMOURD CONNECTIONS.

FIG. 2.—MOTOR PANEL WITH VERTICAL ARMOURD CONNECTIONS.

each case there would be no necessity for tails to intervene between these component parts of any installation.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelopes.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

#### QUESTION No. 1,339.

From an E.H.T. three-phase supply, with static transformers, three phase, six-phase primary delta connected, secondary star connected, it is required to take a large amount of power—single-phase L.T. and H.T.—without unbalancing the three-phase supply. What is the best way to do this, and is it possible without using rotating machinery? Also, could a small amount of single-phase power be taken without using rotating machinery, and, if so, how much? What is the effect of unbalancing a three-phase circuit?—"TRANSFORMER."

(Replies must be received not later than first post, May 22nd.)

#### QUESTION No. 1,337.

Coal Mines Act Electrical Rules.—Rule 14, C (1), requires "the thorough examination of all apparatus (including the testing of earth conductors and metallic coverings for continuity) as often as may be necessary to prevent danger; and (2) the examination and testing of all new apparatus, and of all apparatus re-erected in a new position in the mine before it is put into service in the new position." Under ordinary circumstances how often will it be advisable to test earth conductors and metallic coverings, and what other "examination and testing" is necessary on the following plant? How may we prove that we have continuity and suitable carrying capacity of all armour and earth conductors? We have two 2,000-kw. generators, 3,000 volts, 40 cycles, three phase; current is transmitted at this pressure to three seams at different depths. In these seams we have haulages working direct at 3,000 volts; also in each seam we have transformers stepping down to 440 volts for pump motors and small haulage, and small lighting transformers 440 to 110 volts. The cable from the H.T. switch-board in the power-house to each seam is three-core, paper-insulated, lead-sheathed, and double-wire-armoured; it is fixed to sides of shafts by wooden cleats, and the shaft is comparatively wet. We use the lead sheath and armour as our main earth connection to surface earth plate. The shaft cable is led to a distribution board in each seam, from which all cables in use are also double-wire armoured, and the armour in every case is used as main earth wire between each motor, &c., and main cable armour to surface. I may mention here that in some places the cables are buried in the ground. We have two C.I. earth plates at the surface, and one in the sump at each seam. We transmit about 600 kw. into each seam. The depths of the seams below surface are 400 yards, 500 yards, and 680 yards. At each motor we connect up the switch, controller, motor frame, &c., to a common copper earth wire, and this to armouring of cable by means of W.I. clamps, as, of course, we cannot solder terminals on here underground.

"ASSISTANT ELECTRICIAN."

As no reply deemed sufficiently complete for an award has been received, this question will remain open for replies till May 29th. Competitors should not only indicate the necessary tests for earthing arrangements, armourings, &c., but should also indicate what examination is required of other apparatus, including motors, switches, distributing boards, gate-end boxes, &c.

## ANSWERS TO CORRESPONDENTS

**P. STUART.**—The arrangement you suggest with Leclanché cells will not work. We should recommend you to make inquiries from the Corporation Electricity Department whether they can make arrangements for charging a small battery of accumulators for you if they cannot bring a main to your house. Alternatively a small water-motor would be the best to use to drive your dynamo for supplying a few small lamps occasionally. Any good firm of electrical contractors in Birmingham would probably be able to advise you on this.

**W. H. BROWN.**—In reply to your inquiry as to a method of neutralising electric charges formed on silk or woollen materials during the process of manufacture, probably a similar apparatus to the "Chapman" neutraliser, which is used for a like purpose in printing and paper-making machinery would suit your purpose. This apparatus "Neutraliser" consists of a small motor with slip-rings to supply an alternating current to a high-voltage transformer, one terminal of the secondary of which is connected by rubber-insulated cable to a series of needle-points placed just above the sheet as it enters and leaves the press. A brush discharge is produced, and this apparently causes the paper to lose its charge. One transformer will supply a number of machines. The sole agent for this device in this country is Mr. John Robertson (Wardrobe Chambers, 146 Queen Victoria Street, E.C.).

### ELECTRIC SIGNS.

**T**HERE has been very great improvement lately in the construction of electrically-illuminated signs, which are proving a very successful method of advertising. The expense of running these has been greatly reduced by the employment of metal filament lamps, such as the Osram, with its strength, life, retention of illuminating power and low consumption of current. The General Electric Co., Ltd., send us particulars of a fine example in a sign which has been built for Messrs. Mann, Crossman and Paulin, Brewers, on the Marshes, Stratford, E., and is said to be one of the largest of its character in this country. The length of the sign is 100 ft. and the height from the bottom of the hoarding to the top of the figure of the girl is 42 ft. It stands 10 ft. out of ground, so that the total height is about 52 ft. The number of Osram lamps used for illuminating the sign is as follows: 100 250-volts 32-watts, 176 105-volts 10-watts, and 2 205-volts 17-watts. In the winter months these lamps are kept burning at least six hours each day, and during the summer months three and a half hours per day, approximately 1,700 hours per annum. The lamps are fully exposed to all conditions of weather, and, we understand, have given every possible satisfaction. The sign was erected by the Borough Theatre Billposting Co., Ltd., of Romford Road, Stratford, London, E., and the electrical work in connection with it was carried out by the West Ham Corporation Electrical Department.

**Newcastle Local Section of the Institution of Electrical Engineers.**—The following list of officers for the next session is submitted by the committee:—*Chairman:* Mr. C. Vernier (Mains Engineer, Newcastle Electric Supply Co.). *Vice-Chairmen:* Messrs. P. V. Hunter (Merz & McLellan) and J. H. Holmes. *Past Chairmen:* Messrs. C. Faraday Proctor, C. S. Vesey Brown, and W. C. Mountain. *Committee:* Mr. W. McLellan, Mr. R. P. Sloan (N.E.S. Co.), Mr. C. Turnbull (Tynemouth Corporation), Mr. G. Stoney (C. A. Parsons & Co.), Mr. A. H. Marshall (Cleveland & Durham Power, Ltd.), Mr. J. R. Andrews (P.O. Telegraphs), Prof. W. M. Thornton (Armstrong College), Prof. H. Stroud (Armstrong College), Mr. J. R. M. Elliott (P.O. Telegraphs), Mr. A. P. Pyne (Palmer's, Ltd.), Mr. G. L. Drury (N.E.R. Co.), Mr. J. A. Anderson, Mr. C. H. Davidson (C. A. Parsons & Co.), Mr. E. Fawcett (N.E.S. Co.). *Hon. Treasurer:* Mr. W. A. Clatworthy. *Hon. Secretary:* Mr. H. W. Clothier. *Assistant Hon. Secretary:* Mr. W. G. Guns. *Hon. Auditors:* Mr. H. L. Riseley and Mr. F. O. Hunt. The annual general meeting will be held on May 26th.

**A Turbo-generator Burst.**—A 5,000-kw. Zoelly turbo set in the Essen power station of the Rheinisch-Westfälische Elektrizitätswerke flew to pieces on March 8th last, shortly after being switched off the bus-bars. The set ran at 1,000 r.p.m., and generated at 5,250 volts. An intermittent noise, with a simultaneous variation in the load taken by the generator, was noticed just before the machine was taken off the bars, and almost immediately afterwards it flew to pieces. According to the *Elektrotechnische Zeitschrift*, the various parts of the generator were thrown in all directions, but no one was injured. A portion of the stator, weighing several tons, flew through the wall out on to the street and tore up the tramway lines. Five of the poles of the rotor, weighing nearly a ton each, were thrown through the roof of the station, while the remaining seven were found in various parts of the engine room. A 5,000-kw. machine adjacent to that destroyed was set on fire, but none of the other machines were seriously damaged, and the supply was interrupted for only five minutes.

### SOME ELECTRICAL INSTRUMENTS

THE issue of four new catalogues by Evershed and Vignoles, Ltd. (Acton Lane Works, Chiswick), gives us an opportunity of reviewing a few features of some of the beautifully-made apparatus which has been developed by the firm.

Taking first their recording instruments, we find that the principal feature is the use of the Murday patent pen, somewhat resembling a drawing-pen held nearly horizontally, and carried on knife edges in a stirrup at the end of the hand. The motion of the latter being at right angles to that of the chart, the pen is adapted to mark equally well in either direction. The use of this pen gives to the chart record rectangular co-ordinates (in the roll-chart and drum-chart forms), instead of the usual curved hour-lines. In the disc-chart form the hour-lines become radial straight lines, a fact which makes the disc-chart type for the first time a practical instrument. In the circular-chart recorder (Binstead's patent) the paper disc is supported at its centre on a vertical axle, which is rotated by the clock and carries with it the chart. The chart would thus be horizontal, but as the only portion which is required to be so is the diameter on which the pen is recording, the front and back portions of the chart are bent downwards and are kept in position by guides. This arrangement causes the chart to be very rigid at the portion where the record is being produced, and also enables the recorder to be quite compact. Both the drum and disc patterns of recorders are listed as ammeters and voltmeters with movements of the moving coil and moving iron patterns. Portable as well as switchboard patterns are made.

The list of portable indicating instruments contains a considerable number of patterns of moving coil voltmeters, ammeters, and combined ammeters and voltmeters, many of which have several different ranges. Special cell-testing voltmeters are included, as well as ammeters and voltmeters on the moving iron principle. Another special feature is a range of portable dynamometer-type ammeters, volt-meters and wattmeters. These, when used for alternating currents, are sometimes combined with portable current transformers.

Another list gives particulars of "Foster" pyrometers in practical forms designed for the use of engineers. These are of the thermo-junction type with direct-reading indicating instruments or recorders. The couples are made from "Hoskin's" alloys, one member consisting of an alloy of nickel and chromium and the other of an alloy of nickel and copper. For the very highest ranges the latter is replaced by pure nickel. Among the purposes for which they may be used are to measure temperatures of superheaters; hot-air mains of blast-furnaces; galvanising, tinning or lead-baths; recalcence points of steel; hardening, tempering and carbonising furnaces, and molten brass, gunmetal or iron.

Last, but not least in importance, we have a new catalogue of the famous Evershed testing-sets for insulation and conductor resistance, including the whole chain of instruments from the Megger, with its self-contained generator for measurement at or above working pressure of the highest insulation resistance, conveniently measurable in ohms, the Bridge-Megger set with auxiliary resistance-box for lower resistances, conveniently measured in ohms, to the more recently introduced form of potential ohmeter—the Ducter—for still smaller resistances, conveniently measured in microhms. Descriptions of all these instruments have been published, and it is unnecessary to recapitulate their many ingenious details here. Those desiring full information as to their uses, particularly of the Megger, are recommended to apply to the firm for a copy of the interesting catalogue which we are reviewing.

### AN ENCLOSED SWITCH PANEL

A NEW line of "Mistake-proof" panels has recently been designed by the General Electric Co., of 67 Queen Victoria Street, E.C., embodying several points of interest. As will be seen in the figure, the isolating links and 'bus bars are contained in a separate compartment situated on top of the cubicles. In some earlier types of gear there was the possibility of coming into contact with some live section of the 'bus bars or links when access was gained to the cubicle. In this improved pattern the 'bus bars and the live contacts of the isolating links are partitioned off the remaining portion of the main cubicle by solid metal barriers, thus making it impossible for anybody to accidentally come into contact with live metal: cleaning and adjusting can

therefore be carried out in safety. The second point of importance is that the isolating links are firmly locked in position during the time the panel is in commission. The operation of the links from the front of the board is a feature which will be appreciated by engineers, this doing away with the necessity of opening the cubicle doors to isolate that particular cubicle. The interlocking of the

G.E.C. "MISTAKE PROOF" SWITCH PANEL.

various pieces of apparatus is arranged in such a way that it is impossible to open or close the circuit with the links—the opening and closing of the circuit can only be done with the oil switch, a point which is of the greatest importance. As in previous patterns of G.E.C. high-tension panels, neither marble or slate enter into the construction of the board, the 'bus bars, terminals and isolating links being supported on porcelain insulators. The framework and panels are of boiler plate, rendering the whole fire-proof. No special foundations are required, and this, together with the fact that the whole of the gear is concentrated in the panel, reduces the erection cost to a minimum.

**Sterilisation of Milk.**—We learn from the *Electrical Review and Western Electrician* (Chicago) that the use of ultra-violet light for the sterilisation of milk has been the subject of an investigation carried on in the Bureau of Animal Industry, Washington, by S. Henry Ayers and W. T. Johnson, jun. The milk was picked up from a trough in thin layers by two drums revolving at adjustable speeds. The ultra-violet light was produced by a quartz-tube mercury-vapour lamp taking 3.5 amperes from a 220-volt D.C. circuit. This tube was four inches above the surface of the drums. The average thickness of the layer of milk was 0.1 mm., and the time of exposure was about two seconds at the slower speed of the drums, and one second at the higher speed. While great reductions in the number of observed bacteria were obtained by this apparatus, in which the temperature of the milk during exposure was never higher than 30° C., the results indicated that it is not possible to sterilise milk completely by this means with lamps of the present power and construction. It was further found that when the milk was exposed under conditions suitable for a large reduction in the bacterial content, there was also produced an abnormal, disagreeable flavour, which would render milk unsaleable.

## THE INSTITUTION OF ELECTRICAL ENGINEERS

THE following awards of premiums and scholarships have been made by the Council of the Institution of Electrical Engineers:—

The *Institution Premium* (£25) to Mr. A. E. Hadley, for his paper, "Power Supply on the Rand"; the *Ayrton Premium* (£10) to Mr. F. H. Whysall, for his paper, "The Use of a Large Lighting Battery in connection with Central Station Supply"; the *Fahie Premium* (£10) to Mr. A. J. Aldridge, for his paper, "Practical Application of Telephone Transmission Calculations"; the *John Hopkinson Premium* (£10) to Dr. E. Rosenberg, for his paper, "Self-synchronising Machines"; the *Kelvin Premium* (£21) to Messrs. C. C. Paterson, E. H. Rayner, and A. Kinnes for their paper on "The Use of the Electrostatic System for the Measurement of Power"; the *Paris Premium* (£10) to Mr. J. S. Peck, for his paper, "Earthed v. Unearthed Neutrals on Alternating-current Systems"; an *Extra Premium* (£10) to Mr. M. Solomon, for his paper, "Yellow Flame Arcs"; an *Extra Premium* (£5) to Dr. A. C. Michie, for his paper, "The Formation of Deposits in Oil-cooled Transformers."

Two Salomons Scholarships (£50 each) to Mr. G. G. Dawson, of University College, London, and Mr. Robert Burleigh, of the City and Guilds (Engineering) College, South Kensington, and a David Hughes Scholarship (£50) to Mr. J. H. Lee, of King's College, London.

*Students' Premiums*:—Mr. H. R. Constantine, £10, for his paper, "Time Limits"; Mr. J. Hacking, £10, for his paper, "Phasing Out of Alternating-current Apparatus"; Mr. C. H. Goulden, £5, for his paper, "Low and Mixed Pressure Turbine Plants"; Mr. S. N. C. K. Whitehead, £5, for his paper, "Individual Electric Driving in a Modern Weaving Shed"; Mr. P. Grice, £5, for his paper, "Heating and Cooling of Electrical Machinery"; Mr. A. T. Robertson, £5, for his paper, "Winding of Electrical Machinery."

### TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

Another new automatic telephone system is being introduced into this country. It has been developed in Sweden, and bears the name Betulander. The rights in the system for every country except Sweden have been acquired by Marconi's Wireless Telegraph Co., who will manufacture the apparatus in England, and Mr. C. B. Clay (late London Superintendent of the National Telephone Company) is managing the business for them. The Betulander system has some points of similarity with the Strowger, but the horizontal field of the Strowger switch is not employed, and each line selector and connector switch is removable from the rack without even the loosening of a screw being necessary; connection is made by contacts on the mounting plates registering with springs fitted on the rack. This should greatly facilitate and accelerate repairs and maintenance, especially in small exchanges. The finger-plate dial is not advocated for the subscriber's instruments, but a set of levers, one for each digit, are set, and the removal of the telephone from the switch hook releases them and they make the necessary successive contacts. Fig. 1 shows the construction of the subscriber's set. At the exchange a set of

FIG. 1.—SUBSCRIBER'S SET, OPENED.

four relays are allotted to each subscriber. One of these is used only to connect the ringing current to the subscriber's line when he is called, and the other three are for receiving the impulses from the "actuator" of the subscriber's set and

transmitting them to the various selectors. The first of these is a pre-selector, which chooses an idle trunk to a group selector for the first digit, and this works very rapidly, as the vertical arm holding the wipers falls by gravity; a wheel passes over a set of horizontal wires, to which the trunks are connected, and as soon as it reaches an idle one a magnet operating against a strong spring is de-energised and the wipers are pressed hard against the wires in question. Each group selector has an auxiliary selector permanently allocated to it, the function of which is to seek for an idle selector in the next group, which in its turn responds to the next series of impulses sent out from the actuator, and so on through the whole of the selectors necessary to find the called subscriber.

The general construction of the pre-selectors, the group selectors, and the unit's selectors is similar, and they only differ in small details. Fig. 2 shows a pair of group selectors;

FIG. 2.—A PAIR OF GROUP SELECTORS.

FIG. 3.—GROUP SELECTOR IN SIDE ELEVATION.

the magnet is seen at the bottom, and the set of contacts and wipers on the top. Fig. 3 shows a group selector in side elevation.

It is seen that the system is simple and extremely flexible, and that it allows the equipment to be in exact agreement with the actual number of working subscribers' lines, which is a great advantage. Another feature of the system is that, when the wanted line is engaged, the selector immediately restores it to the normal without waiting for the subscribers to hang up their telephones, so that a low percentage trunking can be employed.

A model exchange is on view at Marconi House (Strand, W.C.), and a 1,000-line plant is on exhibition at 38 rue Lepelletier, Paris.

Negotiations are still proceeding between the Hull Corporation and the Postmaster-General in regard to the ultimate fate of the Hull Corporation telephone undertaking. At the last meeting of the Telephone Committee it was stated that the negotiations are being conducted amicably, although several matters are outstanding. The underlying idea of the negotiations is that the Corporation should purchase from the Post Office the plant required by them from the National Telephone Co. in the Hull area, and continue to work the Hull system there itself.

At the last meeting before the Whitsun recess of the Marconi Committee, Mr. Marconi gave evidence in which

# "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

## Specifications Published May 8, 1913

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

27,793/11. **Advertising.** H. K. HARRIS. A number of advertisements, &c., are mounted on bands or frames, and the position of these can be controlled from a distance by selectors from the central station. For this purpose two circuits, or a single circuit with polarised magnets, may be used, the contacts being controlled by a Wheatstone telegraph tape, or Jacquard or other means. Twenty-one figures.

6,550/12. **D.C. Transformation.** BROWN, BOVERI. To transform high-pressure direct current to low pressure or into mechanical energy, a high-pressure series motor is used, on which is also an exciting winding fed in shunt from a low-pressure dynamo coupled to the high-pressure motor. The dynamo excitation is provided by a shunt winding and an auxiliary winding in series with the motor series winding, so as to ensure self-excitation on starting up and to raise the dynamo E.M.F. at heavy loads. Modifications embracing a Ward-Leonard set may also be used. Five figures.

9,309/12. **Pupin Loaded Cables.** W.E. Co. (W.E. Co., U.S.A.). Pupin coils for loaded submarine telephone cables are made up in long moisture-proof cases. These are joined into the cable during laying, and the end plugs which close the casing are welded to it after the coils and connections are in place. To this end the plugs are provided with recessed faces for the application of water-jackets during welding. Six figures.

9,644/12. **Self-synchronising Machines.** E. ROSENBERG. The method of starting and synchronising synchronous machines described by Dr. E. Rosenberg in a recent I.E.E. Paper (ELECTRICAL ENGINEERING, April 24th, p. 225).

11,439/12. **Drawing Tungsten Filaments.** DEUTSCHE GAS-GLÜHLICHT. During the process of hot-drawing tungsten filaments, the heated wire is passed through dehydrated acids or their salts which are viscous at the temperature of the wire as it enters the die. The use of boric and phosphoric acids is claimed.

11,455/12. **Squirted Tungsten Filaments.** J. A. SCOUAR and DICK, KERR & Co. Viscous sodium silicate solution is used as a binding agent. The intimate mixture is calendered, squirted and dried. The raw filaments so formed are baked in an inert atmosphere and sintered in one operation in an electric resistance furnace.

16,865/12. **Filament Holders.** M. BAUM. Metal wires with a low fusing-point, after being annealed in a reducing gas, are electrolytically coated with chromium and chromous hydroxide and again annealed in a reducing gas at high temperature.

19,288/12. **Rendering Tungsten Ductile.** WESTINGHOUSE METALLFADEN GLÜHLAMPENFABRIK. The metal is heated to over 2000° C., and placed in an inert gas at between 50 and 150 atmospheres, where it is allowed to cool very slowly—during five to ten hours.

## Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad. Summaries of some of the more important of these patents will appear in our next issue.

**Arc Lamps:** BLONDEL [Electrodes] 14,741/12; GENERAL COMPOSING Co., Ges., 28,503/12.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** W.E. Co. (W.E. Co., U.S.A.) [Moisture-proofing cord conductors] 16,152/12; B.T.-H. Co. (G.E. Co., U.S.A.) [Circuit protective gear] 20,663/12; HENLEY'S TELEGRAPH WORKS and NICHOLS [Joint-boxes] 28,094/12.

**Dynamos, Motors, and Transformers:** MOWER and HALE Supplying filtered air] 19,792/12; SCOTT [Commutators] 20,828/12; PINTSCH'S ELECTRIC MFG. Co. and VIDAL [Brush-rockers] 21,433/12.

**Heating and Cooking:** KIRKWOOD [Temperature regulation of electric heating and cooking apparatus] 9,515/12; LOFQUIST [Heating houses] 25,104/12.

**Ignition:** KETERING [Starting systems] 1,424/12; JOHNSON (F.I.A.T.) [Starting systems] 15,069/12; RIKER [For motor vehicles] 22,197/12; BOSCH [Automatic timing] 24,665/12.

**Incandescent Lamps:** WESTINGHOUSE METALLFADEN GLÜHLAMPENFABRIK [Metal Filaments] 26,289/12.

**Switchgear, Fuses and Fittings:** REID [Time switches] 1,693/12; TROOD and DALE [Ceiling roses] 9,910/12; WYNNE [Switches] 13,455/12; FONTECHA [Motor starters] 13,781/12; CHRISTIANS [Fuses] 19,533/12; POOLE [Control of pressure and current regulators] 1,765/13.

**Telephony and Telegraphy:** DEWHIRST [Disinfecting telephones] 9,338/12; JENSEN [Type-printing telegraphs and circuit-selecting apparatus] 18,985/12; MOLINA [Controlling apparatus for automatic telephone systems] 21,008/12; SIEMENS BROS. (Siemens & Halske) [Telegraph tape perforators] 942/13.

**Traction:** LEITNER [Petrol-electric] 9,416/12; McCLOSKEY [Railway block instruments] 20,254/12; TYER & Co., FIRTH and LEAKE [Railway signalling] 29,890/12.

**Miscellaneous:** BLOXAM (Russische Ericsson) [Devices for controlling mechanisms] 7,168/12; GRAY and BURNSIDE [Gyroscopes] 8,952/12; PORTER and ISAACS [Fire-alarm systems] 10,278/12; DENNEY [Fire, and police call boxes] 13,198/12; MALSON [Blasting detonators for coal mining] 15,600/12; ARMORDUCT MFG. Co., JEARY and ANNACKER [Vacuum cleaners] 20,269/12; B.T.-H. Co. (G. E. Co., U.S.A.) [Manufacture of quartz articles] 415/13; PAUL [Gyroscopic position indicators] 5,965/13.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Arc Lamps:** HALBERTSMA, 8,597/13.

**Incandescent Lamps:** MOORE LICHT A.-G. [Moore vacuum lamps] 1,218/13 and 8,712/13; VEREINIGTE GLANZSTOFF FABRIKEN [Manufacture of filaments from cellulose] 2,992/13; JUST [Filaments] 8,966/13.

**Switchgear, Fuses and Fittings:** HELFENSTEIN [Tramcar collectors] 8,267/13; CLOBIUS [Contact and alarm device] 8,741/13.

**Telephony:** PALMER [Transmitters] 8,841/13; SIEMENS & HALSKE [Registering circuits for automatic systems] 9,168/13.

**Traction:** GALLUSSEY [Electrically controlled air-brake valve] 8,865/13; ANGUS [Railway signalling] 9,090/13 and 9,103/13.

**Miscellaneous:** SOC L'ECLAIRAGE ELECT. [Electric driving mechanism for textile machinery] 3,759/13; NATHORST [Magnetic separators] 8,485/13; KEEN [Combined moving-mark target and automatic indicator] 8,603/13; HANTIER [Gyroscopic apparatus for power transmission] 8,846/13.

The following Amended Specification may now be obtained.

27,697/11. **Burglar Alarms.** A. RICHON.

## Amendment of Specification allowed

20,107/11. **Telegraphy.** W. S. STELJES. This specification has been amended practically as required. It deals with receivers of column or tape printing telegraphs, in which the various operations are effected or assisted by the energy stored in springs by the transmitted signal.

## Opposition entered to Grant of Patent

16,821/12. **Adjustable Lamp Fitting.** J. M. WALLWIN. An adjustable telescopic lamp fitting for sewing machines.

## Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

**Dynamos, Motors, and Transformers:** W. T. STUTCHBURY and C. GORICK [Step-down transformer for heating, especially for melting type metal] 1,948/02; B.T.-H. Co. (G.E. Co., U.S.A.) [single-phase commutator motors: an auxiliary stator winding short-circuits the rotor brushes] 1,483/04; R. K. MORCOM and J. M. WALSH [Adjustable choke coil to give varying power factor, especially for testing alternators] 1,517/07; B.T.-H. Co. (J. E. Voeggerath, U.S.A.) [Collector rings for homopolar dynamos] 1,709/08.

**Electrochemistry:** F. SALZER [Obtaining chromium by electrolysis of chromic acid and chromic oxide] 1,344/08.

**Ignition:** H. PRIEPER [Spark intensity is varied by an adjustable-series inductance] 1,699/06; L. A. GIANOLI [Magneto ignition for V-twin-cylinder engines] 1,952/07.

**Incandescent Lamps:** H. KUZEL [Attaching filaments to leading-in wires] 25,994/06; B.T.-H. Co. (G.E. Co., U.S.A.) [Filament mounting machine] 1,585/07.

**Meters:** F. CONRAD [Construction and winding of A.C. induction meters] 923/05.

**Switchgear, Fuses, and Fittings:** C. A. PARK and C. L. MASON (L.N.W. Rly.) [D.P. electro-magnetic switch for train lighting] 1,596/07.

**Traction:** C. I. EARLE [Tramcar trolley retrievers or catchers] 1,224/05; R. BROWN [Surface contact stud switches] 1,818/06; SIEMENS DYNAMO WORKS and F. LYDALL [Preventing over-running of signals] 1,517/08.

**Miscellaneous:** W. T. STUTCHBURY and H. R. SCHULTZ [Electro-magnetic space control in type-casting and composing machines] 1,983/02; W. T. STUTCHBURY and C. GORICK [Details of electric type-casting and composing machines] 1,985/02; A. F. BERRY [A.C. pot-type electromagnets] 2,067/06; R. BERRENBURG [Combined motor rotary pump and whistle] 1,601/08; J. H. FAULENER [Signalling intended movements of a vehicle] 16,293/08.

# ADAMS IGRANIC

CONTROL GEAR FOR COMPRESSORS.

ADAMS  
M<sup>FG</sup> C<sup>O</sup> L<sup>TD</sup>  
BEDFORD  
AND  
LONDON

he detailed the development of the Marconi system since his application for his first patent in 1896. Largely, of course, this was a tribute to his own scientific and commercial progress, and did not bear so directly on the point before the Committee, but in respect of the agreement for the Imperial wireless telegraph scheme, Mr. Marconi expressed the view that the Marconi long-distance system of to-day comprises a number of patents quite as important for their purpose as the famous No. 7,777 of 1896, and it was, he said, the benefit of these, together with the benefit of his own experience and that of some 200 engineers associated with his company, which the Government would receive under the agreement. The rest of Mr. Marconi's statements consisted of comments upon previous evidence. He first complained of the Admiralty statement that their wireless system is an improved Marconi system, and stated that a battleship installation which he inspected in September, 1911, was the Marconi system pure and simple. Much also had been made of the fact that the Marconi system was the spark system, and that there were advantages in other systems which did not employ a spark, but Mr. Marconi informed the Committee that there is now at Clifden a system utilising continuous waves and employing no spark whatever, yet it was still a Marconi system. Dealing with the automatic working which the Committee had been led to believe was new, it was used by him in his Atlantic service, and it was only out of use to-day because the demands of the traffic did not need it. Immediately it was required it would be put into use for transmitting and receiving across the Atlantic. Coming to the report of the Technical Committee, Mr. Marconi commented upon the statement that the Poulsen Co. might be able to erect a 2,000-mile station with the advice and assistance of the Government technical experts. In view of the Post Office statement that they have not the staff for this work, Mr. Marconi assumed that any such advice would come from the Admiralty; if so, it would be a violation of the terms of the present agreement between the Admiralty and the company. Mr. Marconi's next point was that nothing had been said to the Committee by witnesses who knew, of the working of the Coltana station of the Marconi Company in Italy over a distance of more than 2,000 miles over tropical lands. Indeed, Sir Henry Norman, who had actually been in the station at a time when it was so communicating, told the Committee that he did not know of the existence of any station working over 2,000 miles in tropical countries. Finally, Mr. Marconi emphatically protested against the inquiry by the Committee into the affairs of his company which have no bearing on the Committee's terms of reference, and regretted that the services which his company have rendered to the various British Government departments had not been deemed worthy of higher consideration, a remark which was received by loud applause in the Committee room. Only a few questions were asked of Mr. Marconi by the members of the Committee, but the fact was elicited that the terms of the original agreement cannot now hold for various reasons, among them being an increase in the price of raw materials.

In the House of Commons just before the recess, Sir J. D. Rees asked the Postmaster-General whether the Technical Committee which had reported as to the Imperial wireless telegraph scheme had expressed any opinion for the Postmaster-General's guidance supplementing the cautious expression of opinion contained in the report. He also wished to know what evidence there was as to the estimated cost of equipping stations on the Marconi, Poulsen and Goldschmidt systems, and the relative cost of working by each. The reply on behalf of the Postmaster-General was that he had no further information beyond that contained in the report, and that the question of cost did not come within the terms of the Technical Committee's reference.

A meeting of the Liverpool and District Amateur Wireless Association was held on May 8th at the Creamery Café, 56 Whitechapel, for general discussion and exhibition of apparatus. This Association, the subscription to which is 5s. per annum, besides holding fortnightly meetings, arranges visits to works, &c., and among its objects are the purchase

of apparatus for the use of members and eventually to equip a central club with a complete outfit. The hon. secretary is Mr. S. Frith, 6 Cambridge Road, Crosby, Liverpool.

New wireless telegraph regulations have been made, according to the *Board of Trade Journal*, regarding islands in the Western Pacific, requiring, except in the New Hebrides, that licences be obtained from the High Commissioner before a station can be established. Certain rules have also been issued for regulating the use of wireless telegraph apparatus on merchant ships in the Western Pacific.

A decree has been published (which may be seen at the Commercial Intelligence Branch of the Board of Trade) providing for the Government organisation of wireless telegraphy in Brazil. The international stations will include one at Belem and one at Cape Santa Martha, with a range of 4,000 miles, and another at Rio de Janeiro with a range of 2,000 miles.

The Seattle-Sitka cable was put into working order on 6th inst., and the lines of the Indo-European Telegraph Company between Kertch and Soukhoumkaile were repaired on the 7th inst.—The Otranto-Valona cable was restored on 11th inst.

## ELECTRIC TRACTION NOTES

The Leeds Corporation Tramway accounts for the year ended March 31st, 1913, show a net profit of £61,874 after providing for capital charges and the sum of £41,752 for permanent way renewals. The surplus is to be paid over in relief of rates.

The result of the past year's working of the Belfast Corporation Tramways is a net profit of £16,393, after meeting capital charges and adding £13,000 to depreciation.

Out of the 372 vehicles which took part in the annual parade of commercial motor vehicles organised by the Commercial Motor Users' Association on Whit Monday were six electric vehicles, comprising two "Edison-Anderson" vans, entered by the Edison Storage Battery Co., and four "Walker" vans, entered in the new vehicle section by Harrods, Ltd.

By an agreement drawn up by the Manchester Electricity and Tramway Committees, the price to be paid for tramway energy is, for a period of three years, to be at the rate of 1d. per unit for coal 11s. per ton, with an increase or decrease of 0.02d. per unit in respect of each shilling increase or decrease in the price of coal. This charge is to apply to a consumption up to 3,000,000 units per annum, and all supply beyond this quantity will be at the prevailing rate charged to industrial power users under similar conditions of supply.

## LOCAL NOTES

**Birmingham: New Power Station.**—The Electricity Committee's report, referred to in our Tenders Invited column last week, has been adopted by the Corporation. During the discussion upon it, it was suggested that if the advice of the Gas Department had been sought, a better result might have been obtained, apparently from the point of view of reducing the possibility of the smoke nuisance, the argument being that gas engines should be used. The Chairman of the Electricity Committee, however, pointed out, from the detailed investigations carried out by the Committee, it was clear that the results from gas engine plant would not be so good as from steam turbines.

**Electricity Accounts.**—The balance sheet of the electricity undertaking for the year ended March 31st shows a net profit of £27,000, notwithstanding reductions in the power charges which amount to £28,000 for the year. It has been decided to transfer £21,634 to relief of rates and add the balance to renewals account.

Home Office, and Indian State Railways.

When corresponding with advertisers, please mention "ELECTRICAL ENGINEERING."

**Bombay: Street Lighting.**—The present contract between the Gas Company and the Corporation for the lighting of the city expires in 1915, and the City Engineer has been instructed to prepare figures as to the comparative cost of lighting by electricity.

**Bray: Diesel Engine Economy.**—It has been reported to the Council that as a result of the installation of Diesel engines, a saving of £2 10s. per night is being made in the fuel bill.

**Cwmaman: Electric Lighting.**—A Board of Trade inquiry was held here last week, in connection with the Council's application for an electric lighting provisional order.

**Dundalk: Electricity Accounts.**—Following out their usual policy of making the revenue and expenditure of their undertaking more or less balance, the Electric Lighting Committee estimate a surplus of £220 for the current year.

**Dundee: Incorporation of Broughty Ferry.**—The Corporation's Bill for the incorporation of Broughty Ferry has received the sanction of a Committee of the House of Commons, and, assuming that this decision is upheld when the Bill comes before the House of Lords, it will mean that the Broughty Ferry electricity works will come under the control of the Dundee Corporation in due course.

**Harwich: Electric Lighting.**—Dr. C. Liebrand has placed a proposal before the traders of Harwich and Dovercourt for an electric lighting scheme.

**Hessle: Electric Supply.**—The Hull Electricity Committee has prepared an agreement embodying the terms upon which they recommend the Corporation to give a supply of electrical energy to Hessle.

**Manchester: Street Lighting.**—The scheme for the improved lighting of the Manchester streets has now been confirmed by the City Council, and there has been a more or less equal distribution as between electricity and gas. Sixteen streets are to be lighted by electricity, the total length of which amounts to 13,621 yards. The plans are in course of preparation with a view to an early commencement of the constructional work, which will be spread over a period of three years. The capital cost is estimated at £15,000.

**New Zealand: Water Power Scheme.**—The contract has been let for the power house in connection with the Government's water-power scheme at Lake Coleridge. The primary object of this scheme is to supply Christchurch, which is sixty-five miles away.

**Nottingham: Electricity Profits.**—Speaking at the last meeting of the Corporation with regard to the decreased contribution from the electricity undertaking to relief of rates, referred to in our last issue, Sir John Turney, Chairman of the Electricity Committee, said that one of the reasons was an increased expenditure of £3,000 on coal due to increased prices. Further, the granting of a flat rate to small consumers has resulted in a reduced income from this class of consumer of £2,400. The present coal contracts could not be renewed at existing prices, and it was anticipated that the coal bill for next year would be £8,000 more than in 1912.

**Oldham: Electricity Accounts.**—The net profit on the electricity undertaking last year amounted to £1,044, compared with £665 in the previous year. This increased result has been obtained in spite of the extra outlay of £900 for coal.

**Radcliffe: Electricity Profits.**—A net profit of £500 is announced upon the working of the electricity undertaking for last year, notwithstanding the effects of the coal strike. The Committee has decided to place this to the reserve fund.

**Redditch: Position of Electricity Undertaking.**—We announced in our issue for April 3rd that the Advisory Committee which was appointed to inquire into the general position of the electricity undertaking made certain recommendations, and that Mr. Ferguson, the manager of the undertaking, had subsequently resigned. The Committee now recommends that a successor should be appointed at a salary of £250 per annum, but at the last meeting of the Council several members expressed the opinion that a competent manager could not be secured at this salary. After some discussion, it was decided to advertise for a successor to Mr. Ferguson at a salary of £300 per annum.

**Rochdale: Electricity Accounts.**—The gross profit on the electricity undertaking at Rochdale during the past year amounted to £11,740, as compared with £10,644 for the preceding year. The net profit is £2,883. This is the lowest since the department began to pay, with the exception of that in the year 1911-12, and it is due to the increased cost of coal, and to additional interest and sinking fund charges upon extensions, the full benefit of which cannot yet be felt. £2,000 is to be allocated to the relief of the rates, and the balance will be carried to reserve. The Electricity Committee have agreed to supply electricity in bulk to Whitworth for five years.

**Swinton: Electricity Accounts.**—The total number of units sold in the district last year was 206,339, as against 159,182 in the previous year. The deficit for the year was £288, but, with decreasing expenditure, there appear to be prospects of a balance in hand in the near future.

**Toronto: Purchase of Supply Co.**—The City Council is proposing to purchase the Toronto Electric Light Co. and also the traction companies in the city.

**Waterford: Electric Supply.**—A good deal has been heard recently of electric supply installations both by the Council and by the local Gas Company. Apparently despairing of a scheme ever being put into force, the Post Office authorities have decided to put in an independent plant for the General Post Office, the contracts for which have already been placed.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

### Generating Stations, Sub-Stations, Mains, &c.

**Australia.**—The Melbourne Corporation requires switch-gear and instruments. Further particulars from Messrs. McIlwraith, McEachern & Co., Billiter Square Buildings, E.C.

**Belfast.**—A loan for new mains and services is to be applied for.

**Bulgaria.**—Three generating sets are required by the Pernik State coal mine. A copy of the specification may be seen at 73 Basinghall Street, E.C.

**Ilkley.**—An electric lighting scheme at an estimated cost of £18,000 is to be prepared.

**Leeds.**—An application has been made to the Local Government Board for sanction to borrow £38,500 for additional generating plant; £100,000 for mains; and £30,000 for sub-station equipment.

**London: L.C.C.**—High and low tension cables. (See advertisement on another page.)

**New Zealand.**—The Devonport Council has sanctioned a company's proposal to establish an electricity works.

The Lytleton Council require two 500-kw. converters, also switchboard panels. May 22nd. New Zealand High Commissioner in London, 13 Victoria Street.

**Rhondda.**—A Local Government Board inquiry has been held concerning a loan of £33,400 for the purposes of the electricity undertaking.

**South Africa.**—The Wellington Council has decided to raise a loan of £10,000 for electric supply purposes.

**Tullamore (Ireland).**—A report on an electric lighting scheme is being prepared for the Council.

**Uruguay.**—According to the *Review of the River Plate*, the Anglo-Argentine Electricity Co. are about to construct a new power house at Concepcion del Uruguay.

**Valparaiso (Chile).**—Tenders are invited for the construction of a generating station distribution system at the Port. Particulars from the Chilean Legation, 48 Grosvenor Square, W.

### Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

**Berwick.**—Cinematograph theatre.

**Croydon.**—Seventeen houses, Melrose Avenue. W. Aston & Co., Thornton Heath.—Eleven houses, Bingham Road. W. Hawkins, Bingham Road.—Cinematograph theatre, Brighton Road. J. P. Oldacre, Purley.

**Stockport.**—Extension of police buildings. Town Clerk.

### Miscellaneous

**Australia.**—The Board of Trade Journal states that tenders are invited by the Electric Supply Department of the city of Melbourne for 20,000 yds. of 3-in. circular section fibre conduits. Particulars from McIlwraith, McEachern and Co., Billiter Square Buildings, E.C.

**Indo-China.**—The establishment of a large wireless telegraph station is contemplated at Saigon.

**New Zealand.**—The New Plymouth Council has decided to raise a loan of £55,000 for tramway extensions.

**Spain.**—The Minister of Marine invites tenders for two long-distance wireless telegraph stations, and two experimental installations.

## TENDERS RECEIVED AND ACCEPTED

**Belfast.**—The tender of Messrs. Babcock & Wilcox for the supply of a boiler, superheater, mechanical stoker and pipe-work at £2,805 has been accepted.

**China.**—The General Electric Co. of China has received an order for an electric supply installation for the town of Fatshan, near Canton. The generating plant will consist of three 200-kw. three-phase high-tension generators, driven by Bolinders oil engines. The plant is expected to arrive in China in July.

**Eastbourne.**—The following tenders have been received for the supply of flame arc lamps for public street lighting:—Electrical Co. (accepted); Engineering & Arc Lamps, Ltd.; Maxim Lamp Works, Ltd.; Siemens Bros. Dynamo Works, Ltd.; Oliver Arc Lamp Co.; Jandus Arc Lamp & Electric Co.; G. Brault; Johnson & Phillips; Ridings Arc Lamp Co.; Union Electric Co.; Electrical Engineering & Equipment Co.

**Manchester.**—Orders for paper insulated and rubber insulated cables have been placed with W. T. Henley's Telegraph Works Co., India Rubber, Gutta Percha and Telegraph Works Co., Siemens Bros. & Co., and C. Macintosh & Co.

**South Africa.**—We learn from the *African World* that the Germiston Council has awarded the following contracts in connection with their trackless trolley scheme:—H. Davis & Co., ten Cedes-Stoll cars, £11,400; converter fittings, £1,328, poles £6,899; Telegraph Manufacturing Co. (Colonial), electric mains, £4,064; S. Sykes & Co., motor-converters, £3,272.

## APPOINTMENTS AND PERSONAL NOTES

The following increases of salaries are recommended by the Dublin Electric Supply Committee:—Mr. M. Ruddle, City Electrical Engineer, from £750 to £1,000 per annum, by £50 increments; Mr. L. J. Kettle, Deputy Electrical Engineer, from £400 to £600 per annum, by £50 increments, and Mr. Gilbert Archer, Chief Distribution Engineer, from £350 to £450 per annum by £25 increments.

The post of Head of the Electrical Engineering Department of the Birmingham Municipal Technical School is vacant. (See an advertisement on another page.)

A manager is required for the Redditch electricity undertaking at a salary of £300 per annum.

The salary of Mr. A. D. Chalmers, Borough Electrical Engineer at Gillingham, will, at the expiration of his present agreement in August, continue to be £300 per annum, but his commission on the gross profits is to be increased from 1 to 1½ per cent.

Mr. R. H. Thompson has been appointed Station Superintendent by the Nelson Corporation, and Mr. J. Stanworth Mains Superintendent.

The salary of Mr. H. H. Smith, Superintendent at the Worcester electricity works, is to be increased from £150 to £180 per annum by £10 increments.

Mr. W. E. Bradshaw, of Clapham, has been appointed Mains Superintendent by the Islington Borough Council, in succession to Mr. T. A. G. Margary. The salary is £200, rising to £225 per annum.

The Rt. Hon. Lord Castletown, Chancellor of the Royal University of Ireland, has been appointed Chairman of the Governors of Faraday House Electrical Training College, in succession to the late Earl of Crawford.

A telephone engineer is required with common battery and automatic exchange experience. (See an advertisement on another page.)

Fitter required for Central station on east coast of Scotland. (See an advertisement on another page.)

## MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. G. Smith and Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £73 to £73 10s. (last week, £72 5s. to £72 15s.).

**Liquidations.**—A private meeting of the creditors of the Adams Manufacturing Co., Ltd., was held on Friday. Mr. Lewis Hardy, the liquidator, said that the works were full of orders, and he quite believed he was carrying on the business at a profit. The statement of affairs showed that after taking machinery and tools, trade fixtures and fittings, patents and patterns and freehold factories at their book value, there was a surplus of assets over liabilities amounting to £5,860. The creditors expressed extreme dissatisfaction with the position. The liabilities amount to £30,094, and the assets, after paying off debentures and preferential creditors, are estimated at £35,954. The directors hold about £13,000 of the £15,000 debentures. The meeting decided to apply to the Court for the appointment of Mr. G. Corfield and a committee of creditors to act jointly with Mr. Hardy. Among the principal electrical creditors may be mentioned Cutler-Hammer Manufacturing Co., £1,181; Rochdale Electric Co., £280; Electric & Ordnance Accessories Co., £226; *Electrical Times*, £174; *Electrical Review*, £113; Electro-Mechanical Brake Co., £116; Acme Electrical Co., £130; Concordia Electric Wire Co., £118.

**Bankruptcies.**—The last day for receiving proofs in the bankruptcy of Cecil Wray, electrical engineer, late of 24 Simes Street, Bradford, is May 21st. The trustee is W. Durrance, 12 Duke Street, Bradford.

The last day for receiving proofs in the bankruptcy of C. S. Northcote, electrical engineer, 67 Stanthorpe Road, Streatham, is May 23rd. The trustee is Mr. E. W. J. Savill, 132 York Road, Westminster Bridge Road, S.E.

## COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

**Callender's Cable and Construction Co.**—The profit for 1912 was £155,619, which exceeds that of the previous year by more than £20,000, notwithstanding the heavy expenditure during the coal and Thames dock strikes. A sum of £8,924 is added to depreciation, and a final dividend, making 10 per cent. for the year, together with a bonus of 5s. per share, is recommended on the ordinary shares, carrying forward £91,745. The Company's business, both in underground mains and telephone cables, shows further signs of considerable extension, whilst the increase in output last year, especially for the Colonies and abroad, rendered it necessary to provide further capital, which has been obtained by the formation of Callender's Share and Investment Trust.

At the meeting on Thursday the Chairman said that the works are at present filled with orders of the widest range, both from at home and the Colonies, and that unless something unexpected happened, as good, if not better, a balance-sheet would be shown next year.

**Willans and Robinson.**—The accounts for the half-year to December 31st, 1912, show that after allowing for debenture interest, and £3,264 for depreciation, there is a small profit of £154. This improved result is mainly due to the increased volume of work, and as during the opening months of the present year further orders have been obtained at better prices, the directors hope for a continuation of the improved position.

**Chloride Electrical Storage Co.**—A dividend of 10 per cent. has been declared for the past year, carrying forward £8,407.

## NEW COMPANIES

**"CEAG" ELECTRIC SAFETY LAMP CO.** Registered by Cruesemann & Rouse, 85 Gracechurch Street, E.C. Capital £10,000. (This Company's safety lamp was described in our issue for September 5th, 1912, page li.)

**STOLZ ELECTROPHONE CO.,** 85 Fleet Street, E.C. Capital, £60,000.

**BRITISH ELECTRIC HEATER CO.,** 103 West George Street, Glasgow. Capital, £50,000.

Cheques to be made payable to THE KILOWATT PUBLISHING CO., LTD., and to be crossed LONDON COUNTY AND WESTMINSTER BANK (Temple Bar Branch).

## SUMMARY

THE annual report of the Institution of Electrical Engineers has been issued, and records a year of great activity. (Page 284.)

THE British Electrical and Allied Manufacturers' Association has issued a set of standard rules for the rating, &c., of electrical machinery. (Page 285.)

AN article by Mr. E. C. Evans describes a method of testing the condition of storage battery plates by measuring the P.D. between either of them and a piece of cadmium dipped in the electrolyte. (Page 285.)

A PARTY of over a hundred members of the Institution of Electrical Engineers, accompanied by about forty ladies, are taking part in a joint meeting with the Société Internationale des Electriciens in Paris. (Page 286.)

OUR "ELECTRICAL ENGINEERING Literary Section" contains a list of new publications, reviews of a number of technical books, and gives a selected list of recommended works on all branches of electrical engineering. (Page 287.)

A QUESTION relating to the testing of electrical machinery in mines is given in our Questions and Answers Columns. (Page 291.)

A SPRING-CLIP shade gallery is described on page 291.

THE Patent Specifications published last Thursday include some dealing with petrol-electric traction, air-filters, control of heating apparatus, commutators, &c.

A patent has been allowed to J. J. Deschamps for an automatic parcel railway system in spite of opposition. (Page 292.)

A SIMPLE lift controller is described, and an example of electric cathedral lighting is illustrated on page 293.

AN expenditure of £1,600,000 is contemplated upon railway electrification at St. Petersburg.—The L.C.C. has been experimenting successfully with Stevens petrol-electric tramcars, and single-deck cars are being agitated for on the Hagley Road route of the Birmingham Corporation tramways.—A London firm is negotiating with the New South Wales Government concerning an underground railway scheme in Sydney. (Page 293.)

WE give some information as to the Australian Government wireless telegraph stations, and also refer to the reception of messages up to 2,400 miles from the Fort Meyer station by a U.S. battleship. Wireless communication has been established experimentally between Berlin and New York, a distance of nearly 4,050 miles. (Page 294.)

THERE is difference of opinion between the Sheffield Corporation and the local wiring contractors as to the interpretation of the Corporation's powers under their Act of last year.—Mr. E. M. Lacey has reported upon the general position of the Walsall electricity undertaking.—The rateable value system of charging is recommended at Gravesend.—The Hebburn Council are asking for a Board of Trade enquiry concerning the safety of electric cables in their district.—Mr. F. Ayton, the Ipswich Borough Electrical Engineer, recommends a tariff to encourage the use of electric vehicles.—The Leeds electricity accounts for last year show a net profit of £15,508.—A refuse destructor scheme in conjunction with electricity supply is under consideration at Rothsay. (Page 295.)

LOANS have been inquired into as follows:—Bridlington, £5,000; Nelson, £4,000; and Yarmouth, £3,840.—Steam and feed piping, &c., is required at Dundee; generating plant for the Bury St. Edmunds Infirmary; 75 new tramcars at Birmingham; a twelve months' supply of stores at Liverpool; and generating plant in Canada. (Page 295.)

THE British Thomson-Houston Co. shows a net profit of £1,208 for the year 1912.—A 3 per cent. dividend is paid on the preference shares of the Urban Electric Supply Co.; and 3½ per cent. on the ordinary shares of the Cleveland & Durham County Electric Power Co. (Page 296.)

**Railway Classification of Electric Stoves.**—Notice is given by the railway companies of Great Britain of an application under the Railway and Canal Traffic Act, 1888, to reclassify electric stoves and heaters for the purpose of rates and charges for carriage. As will be seen by an advertisement elsewhere in this issue, objections can be lodged against the proposal.

## ARRANGEMENTS FOR THE WEEK

THURSDAY, MAY 22ND, TO SATURDAY, MAY 24TH.  
*Institution of Electrical Engineers.*

Continuation of Meeting in Paris.

FRIDAY, MAY 23RD.

*Royal Institution.*

9 p.m. Evening discourse: "The Secret of the Permanent Magnet," by Prof. S. P. Thompson, F.R.S.

MONDAY, MAY 26TH.

*Institution of Electrical Engineers: Newcastle Section.*

7.30 p.m. Annual general meeting at Armstrong College, to be followed by a lecture on "Gas Engines," by A. P. Pyne.

## The London Electrical Engineers.

(To-Day) THURSDAY, MAY 22ND.—C. Company. FRIDAY, MAY 23RD.—D. Company. MONDAY, MAY 26TH.—A. Company. TUESDAY, MAY 27TH.—B. Company. THURSDAY, MAY 29TH.—C. Company. FRIDAY, MAY 30TH.—D. Company. Infantry Drill, 7 to 9 p.m. Technical instruction for all Members on the Sixth Rate and for all Candidates for Higher Rating, 7 to 9 p.m. Musketry Instruction, 9 to 10 p.m.

WEDNESDAY, MAY 28TH. All Companies.—Annual Musketry at Purfleet Rifle Ranges. Railway tickets will be sent to those notifying Headquarters of their intention to attend.

SATURDAY, MAY 31ST.—Headquarters open from 10 a.m. till noon. Annual Musketry at Purfleet. Members are reminded that this is the last date on which they can fire their Annual Course to make themselves efficient, and should apply early for their Railway Tickets.

**Old Centralians.**—A lawn tennis match between the Old Centralians Tennis Team and the City and Guilds (Engineering) College Lawn Tennis Club was played on Saturday at the latter club's ground, North Ealing. The Old Students were beaten by 5-4. The score was as follows:—Regnard (*Captain College Team*) and Saurback lost to R. Burton (*Captain Old Centralians*) and H. T. M. Kent, 3-6, 7-5, 4-6; beat J. V. and P. V. Dupré, 2-6, 6-2, 6-4; beat A. P. Dicksee and R. A. Mack, 6-1, 6-1. Harris and Moore beat Burton and Kent, 6-2, 7-5; lost to J. V. and P. V. Dupré, 1-6, 2-6; beat Dicksee and Mack, 6-1, 6-3. Ryan and Manuel lost to Burton and Kent, 3-6, 1-6; lost to J. V. and P. V. Dupré, 0-6, 4-6; beat Dicksee and Mack, 6-2, 6-3. A return match will be played on June 7th. Old students of the college who are good tennis players are requested to communicate with the match captain (Mr. Richard Burton, c/o Messrs. C. W. Burton Griffiths and Co., 1-3 Ludgate Square, Ludgate Hill, E.C.4.).

**A Shooting Competition.**—On Monday evening last an interesting competition between the Rifle Club of Siemens Bros. Dynamo Works, Ltd., Lamp and Fittings Department, of Dalston, and representatives of the Electrical Press. The competition embraced shooting at a fixed target with Morris tube, and also big-game shooting with a Winchester repeater, 12 shots per minute. In the latter case a springbuck dodged on and off a screen through the agency of the cinematograph, but even in this the Electrical Press were unable to beat the Siemens' team. The scores were: fixed targets, Siemens, 273; Press, 233; and moving targets, Siemens, 61; Press, 54. The maxima possible were 364 and 264 respectively. The competition took place at Life Targets, Ltd. (12 Bow Street, Covent Garden, W.C.), who own the patents for the system. Any suitable cinematograph picture is projected on to a screen consisting of three thicknesses of paper. One is moved horizontally once a day, and serves to keep taut the others, which are moved vertically through about  $\frac{1}{2}$  in. by a solenoid, spring, and ratchet after each shot. As soon as a shot is fired the sound waves, acting on a microphone, cause it to pass a feeble current through a delicate Kramer relay, which in turn instantly stops the cinematograph by applying a brake, which is released after a few seconds by an adjustable dash-pot. The shot perforates the screen, and through the hole so produced a bright light shines. As soon, however, as the cinematograph restarts, the paper is moved forward as stated above, and the picture is ready for the next shot.

**Electric Cooking at West Ham.**—A series of "Tricity" electric cooking lectures and practical demonstrations was commenced by Mr. F. S. Grogan, at the Town Hall, Stratford, on Tuesday afternoon, and, as announced recently in our columns, will be continued daily at 3.30 and 7 p.m. until to-morrow evening. In his usual suave and subtle manner, Mr. Grogan discourses on the unique features of the "Tricity" duplex cooker, its sphere of usefulness, and the adaptability of the various parts for different purposes. Mr. Grogan also points out that it has been conclusively proved that with gas at 2s. 6d. per 1,000 cub. ft., and electricity at 1d. per unit, the costs of cooking by the two systems are the same, while with electricity there is an additional saving of between 20 and 30 per cent. in the weight of meat cooked, the latter, by the way, being cooked uniformly throughout. There are, he said, over 5,000 of these cookers now in use in this country. The West Ham Corporation Electricity Department are evidently making a bid for an increase in their already substantial heating and cooking load, which, with a revised tariff, which we hope to see soon, coupled with the energies of Mr. H. Farndon (Sales Manager), may soon swell to large proportions.

## THE INSTITUTION OF ELECTRICAL ENGINEERS

THE Annual Report of the Institution of Electrical Engineers, which will be submitted to the Annual General Meeting on May 30th, records an increase in the total membership of 547 since last year. The numbers of the various classes of members, &c., are now as follows: Hon. Members, 7; Members, 1,549; Associate Members, 3,535; Associates, 671; Graduates, 260; Students, 1,062; Total, 7,084. There have been during the session fourteen London meetings and sixty-one meetings of Local Sections, as well as meetings at Calcutta and Cape Town. The Students' Meetings in London have numbered nine, and twenty-two have been held in the provinces. The summer meeting last year in Glasgow and the joint meeting now being held with the Société Internationale des Electriciens are referred to, and a list of the premiums and scholarships is given. These were given in ELECTRICAL ENGINEERING, May 15th, p. 277. As already announced, the *Journal* is in future to be published fortnightly, from December to July; it is now stated that it will be of quarto size, and will contain the papers and discussions now published in the *Journal*, notices of meetings of the Institution and of the Local Sections (this will replace the present postcard notices), communications from the Council to the members, and periodical reports on the work of the Council and Committees of the Council.

Notes are given in the Report on the apparatus and facilities available for demonstration purposes in the lecture theatre, and the arrangements whereby members visiting America can use the rooms of the American Institute of Electrical Engineers are mentioned. Other matters dealt with are the scope of the work of the new research committee, the new examination scheme, and the Kelvin memorial window, which will probably be completed in June and handed over to Westminster Abbey in July. Some additions to the Museum and Library are recorded.

The accounts show a margin of income over expenditure of £1,238. Donations and subscriptions to the Benevolent Fund in 1912 amounted to £147.

**Linking Up London Electric Supply Undertakings.**—We referred in our issue for April 17th, p. 212, to a motion by the Battersea Borough Council to restrain the County of London Electric Supply Co. from laying mains in the Borough of Battersea to connect up the Wandsworth and Southwark areas of the Company. This motion was refused, and the appeal came before the Master of the Rolls, Lord Justice Kennedy, and Sir Samuel T. Evans, in the Appeal Court on Tuesday. Under the Electric Lighting Act of 1908 all the London electric supply authorities are authorised to link up their undertakings. Before the passing of the Act the County of London Co.'s Wandsworth and Southwark mains were, and are still, connected by means of mains through the Borough of Lambeth along a route thirteen miles in length. These mains were laid under an agreement with the Lambeth Council, to whom the County of London Co. pay an annual rent of £100. The proposal of the County of London Co. now is to lay a new main between Wandsworth and Southwark through Battersea, the distance being in this case only six miles. The contention of the Battersea Council was that Section 4 of the Act of 1908 only provided for one connecting-link between any two areas, and that when one such link was laid the powers of the Act ceased so far as those particular areas were concerned. Thus it was argued that as a main already existed between Wandsworth and Southwark the Company had no right to lay another. The Appeal Court held, however, that this construction of the words of the Section is wrong, and entered judgment for the County of London Co. with costs.

**Reductions in Cable Prices.**—Reductions in the prices of "Association Grades" of cables have been made by the members of the C.M.A. so that the discounts on 2,500, 600, and 300 megohm grades of C.M.A. and Association pure rubber flexibles are now 27½, 15, and 10 per cent. Reductions are also being made in the prices of non-Association grades, but the new discounts are slightly different from those given above. The India Rubber, Gutta Percha and Telegraph Works Co. and W. T. Henley's Telegraph Works inform us that their discounts for pure I.R. wires and cables are now 7½, 15, and 10 per cent. We also understand that Callender's Cable and Construction Co., British Insulated and Helsby Cables, Ltd., The London Electric Wire Co., and some other firms are making similar reductions in the non-Association as well as the Association cables of their manufacture.

## STANDARDISATION RULES FOR ELECTRICAL MACHINERY

A SET of rules for the standardisation of electrical machinery has been drawn up by a Committee of the British Electrical and Allied Manufacturer's Association, and has been provisionally adopted by the Council.

The first section establishes 50 and 25 cycles per sec. as standard frequencies and 2,000, 3,000, 6,000, 10,000 and 20,000 volts as standard high pressures. The standard generator pressures are given as 115, 230, 460 and 525 volts D.C. and 440, 550, 2,200, 3,300, 6,600 and 11,000 volts A.C., and the standard low pressures at consumers' terminals are given as 110, 220, 440 and 500 volts D.C. and 100, 200, 400 and 500 volts A.C. The section devoted to high-pressure tests and insulation resistance deprecates prolonged tests at high pressure and specifies test pressures of 1,000 volts for rated pressures not exceeding 333 volts; three-times rated pressure with a minimum of 1,500 volts for pressures from 333 to 1,500 volts, 4,500 for voltages from 1,500 to 2,250 volts, and twice the rated pressure for pressures above 2,250 volts. In a similar way very high insulation resistance specification is not recommended since, in order to obtain it, long baking at high temperatures may be required, which may permanently damage the insulating material. The values of one megohm for windings above 350 volts and 0.25 megohm for low-pressure windings are put forward as affording sufficient evidence that the windings are in condition to receive the high-pressure test.

Machines are classified as open, protected, enclosed-ventilated, pipe-ventilated (with or without "forced draught"), drip-proof, totally enclosed or flame-proof. Definitions of these types are given. The section on rating differentiates between "continuous" and "short-time" rating and makes special provisions for the rating of variable-speed machines. Continuous rating of machines is based on a temperature rise after running "until the temperature is practically constant; that is, until the rate of increase of temperature rise does not exceed 1° C. per hour."

The following are the specified temperature rises: Machines with "unobstructed" ventilation; windings or cores in which windings are embedded 40° C., commutators and slip-rings 55° C. These are as measured by thermometer. The rise as measured by resistance of alternator field coil is not to exceed 55° C., and of D.C. shunt field coils 60° C. In the case of machines with "partially obstructed" ventilation the limit is raised to 47° C. for windings, &c., by thermometer, or 65° C. by resistance (for D.C. field coils). A further advance to 55° and 70° C. respectively is allowed for totally enclosed machines. The commutator figure is the same in all cases. The standard temperature rise for transformers is given as 50° C. Special allowances are made for machines for tropical conditions, machines with special heat-resisting insulating materials, and machines for high altitudes. The standard overloads for continuously rated machines are 25 per cent. for machines with unobstructed ventilation, or 15 per cent. for machines with partially obstructed ventilation for two hours for 100 kw. or over, one hour for 25-100 kw., half-hour for 2-25 kw., and five minutes for 2 kw. and under. For totally enclosed machines no overloads are required, except the momentary overloads in connection with commutation tests. Motors on short-time rating are to be capable of 100 per cent. overload for thirty seconds, and transformers are to be capable of 25 per cent. overload for two hours, and 100 per cent. for thirty seconds.

## CADMIUM TESTS ON STORAGE BATTERY PLATES

THE following description of testing the condition of storage battery plates has been sent us by Mr. E. C. Evans. As the maintenance of a battery discharge voltage, and consequently the output, depends on the condition of both the positive and negative plates, it is essential to ascertain that they are always properly charged. The voltmeter readings of individual cells and also the existence of gassing is not always an indication of the completion of a charge, and, therefore, in order to obtain the best efficiency from a battery it is necessary to see that both the positive and negative plates are completely charged. If either are not always fully charged the capacity on discharge will only be equal to that of the least efficient set of plates.

The best method of testing the state of the positive and negative plates in a cell is to obtain voltmeter readings between them and a cadmium stick. A piece of cadmium measuring, say, 3 ins. long and  $\frac{1}{4}$  in. in diameter would be

suitable for the purpose, but it must be free from impurities and allowed to become slightly oxidised before use. As there is a difference in potential between cadmium and cadmium oxide the stick should never be scraped bright during a test, otherwise comparative figures cannot be obtained.

The reading between the cadmium and negative plates will only be small, so that it will be necessary to use a sensitive voltmeter with a finely divided scale in order to obtain accurate results. The ordinary cell-testing type is not suitable as the dial is usually insufficiently graduated for fine readings, and also the resistance of these instruments is generally too low. The reason for using a high-resistance voltmeter is to eliminate errors which would result from polarisation taking place owing to an appreciable current passing between the cadmium test-piece and the plates under test. One of the voltmeter leads should be suitably connected to the cadmium and the latter should be allowed to remain in the acid of the cell for a few minutes before making the test, in order that a coating of cadmium sulphate may form on it. It is also important not to allow the cadmium to dry between taking readings, as this will cause inaccurate results. Care should be taken, also, to see that the cadmium does not come into contact with any of the plates.

The tests should be made with the battery charging at the normal rate, and the readings taken at the beginning as well as towards the end of a charge. At the commencement of charge it will be found that no reading is obtained between the cadmium and negative plates, but as the charge proceeds a P.D. will gradually rise until it reaches the neighbourhood of 0.15 of a volt or over towards the end of charge. The voltaic relations between the cadmium and positive plates and the cadmium and negative plates and also their P.D. values will be as follows, the left hand being the positive side:—

Positive plates and cadmium .....	2.35 volts
Cadmium and negative plates .....	0.18 "
Positive plates and negative plates ...	2.53 "

It will be seen from the above that the cadmium is positive to the negative plates and negative to the positive plates, and that the voltage of the cell is equal to the sum of the two cadmium readings when these are in opposite directions or when the voltmeter leads have to be changed after making one reading before the other is obtained. Should it be found towards the end of a charge that the cell voltage is 2.5 or more and the reading between the cadmium and negative plates is less than 0.15 volt, the charge cannot be considered as complete, and must therefore be continued until it reaches at least the figure mentioned and ceases to increase. If no P.D. is obtained between the cadmium and negative plates the latter are not fully up. Cadmium readings are also very useful in investigating the condition of the positive and negative plates during discharge. In this case the cadmium and negative plates readings are in the reverse direction, the negatives being positive to the cadmium, the cell volts being equal to the difference between the two cadmium readings. During discharge the P.D. between cadmium and negative plates gradually increases until a limit depending on the rate of discharge is reached.

The following table illustrates the various values of the readings obtained from a cell in which the positive and negative plates were in proper condition:—

	Positive and negative plates. Volts.	Positive plates and cadmium. Volts.	Negative plates and cadmium. Volts.
10-hour rate	2 minutes ..	2.07	2.25
	5 hours .....	1.92	2.12
	10 " .....	1.70	1.93
3-hour rate	2 minutes ..	2.02	2.22
	1½ hours .....	1.88	2.10
	3 " .....	1.70	2.00
1-hour rate	2 minutes ..	1.96	2.17
	½ hour .....	1.83	2.09
	1 " .....	1.60	1.93

From the above figures it will be noticed that the cadmium readings vary according to the rate and also the period of discharge, the P.D. between the cadmium and negative plates increasing until the respective limits are reached. If it is found that the final voltage of the cell is obtained before the limit for the cadmium and negative is reached, it shows the positive plates are at fault, whilst should the cadmium and negative figure be obtained before the limit for the cell, the result would prove the negative plates to be the least efficient.

## SMALL INDUCTION MOTORS

FOR ALL CLASSES OF WORKSHOP DRIVING.

PROMPT DELIVERY IN SIZES FROM  
 $\frac{1}{2}$  TO 10 H.P. AT ALL THE USUAL  
 SPEEDS AND PRESSURES.

OPEN, PROTECTED & ENCLOSED TYPES.

HIGHEST GRADE MATERIAL and  
 WORKMANSHIP.

CAXTON HOUSE, WESTMINSTER, LONDON, S.W.

And at MANCHESTER, GLASGOW,  
 and NEWCASTLE.

### THE INSTITUTION VISIT TO PARIS

ABOUT 110 members of the Institution of Electrical Engineers, accompanied by forty-two ladies, arrived in Paris on Tuesday evening to take part in the joint meeting of the Institution with the Société Internationale in Paris, which commenced yesterday and continues until Saturday. Yesterday six Papers on electric traction were discussed, and the visits included an inspection of the large generating station at St. Denis. The day closed with a banquet at the Palais D'Orsay.

A report of the meeting will appear in our next issue.

**Electric Mill Driving in India.**—Further to our recent notice regarding the motor and transformer equipment for the textile and flour mills in the Bombay district, which are deriving their power from the mains of the Tata Company, we are now enabled to give further particulars of the large contract which has been secured by the British Westinghouse Company. The motors are all of the Westinghouse slipring protected type, for 2,000 volts, three-phase, 50 cycles. There are at present a total of 207 motors of this type on order, ranging from 50 to 500 b.h.p., and running some at 290 and some at 365 r.p.m. In the majority of cases they are coupled direct to the line shafting without the intervention of countershafting. The motor pillars are of the Westinghouse ironclad pattern, which are largely used in mining and other industrial work in this country, and starting is effected by liquid controllers. The transformers are three-phase, oil-immersed, self-cooled units, and reduce the supply from 6,000 volts to 2,000 volts for the motors. They number 64 in all, and are of four sizes, thus: 22 of 50 k.v.a., 12 of 500 k.v.a., 21 of 700 k.v.a., and 7 of 900 k.v.a. The mills in which the above-mentioned equipment is to be installed are as follows:—Pearl, Finlay, Simplex, Baigum, Swan, Bombay Cotton, Jamshed, Nahomedbhoy, Pabaney, Crescent, Fazulbhoy, David No. 1 and 2, Down, Standard, Phoenix, Gold Mohur, Jubilee, Crown, Western India, Apollo, Ripon, Dharamsey, Hope, Alliance, Natildas Goculdas, New City of Bombay, Colaba, New Great Eastern, Sun, Bombay Flour, Merchants' Flour, and Union Flour. These brief particulars we present above will give some idea of the importance of this immense stride in textile electrification.

### CATALOGUES, PAMPHLETS, &c., RECEIVED

**ALUMINIUM.**—New leaflets from the British Aluminium Co., Ltd., 109 Queen Victoria Street, E.C., deal with aluminium feeders for electric railways and connectors for stranded aluminium conductors.

**MOTORS.**—A list of small continuous current motors, ranging from  $\frac{1}{2}$  to  $7\frac{1}{2}$  h.p., is to hand from Higgs Bros. (Sherbourne Road, Balsall Heath, Birmingham). These motors are fitted with ball bearings, and are listed both as open and semi-enclosed machines.

**CABLES AND RUBBER GOODS.**—A new list of electric cables and safety insulating appliances is to hand from The St. Helens Cable & Rubber Company, Ltd. (Warrington). In addition to containing full details of the company's well-known "cab tyre" sheathed cables, "Association" cables, flexibles, &c., the list introduces some new items, including a patent electrically heated vulcaniser, specially designed for jointing and repairing cab tyre sheathed cables. Other novelties are insulating gloves, with cab tyre facing, and insulating shoes of a design in which the amount of wear is readily apparent, and a buckle allows for various sizes of feet being used in the same shoe. Rubber switchboard matting is also included. The company announce a reduction of about  $7\frac{1}{2}$  per cent. in the prices of all rubber insulated cables. The illustrations show the large business which the firm is doing with colliery cables, both of the "Dialite" and cab tyre sheathed types.

*Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."*

**RESISTANCES.**—An effective card from the Schniewindt Electric Co. (40 and 41 Staniforth Street, Birmingham) calls attention to the company's special net resistances.

**FANS.**—A catalogue from Pitters' Patents, Ltd. (20 Bishopsgate, E.C.), deals with Pitters' Patent multiblade fan, for which a much higher efficiency is claimed over ordinary fan blades.

**BELL PUSHES.**—A number of artistic and novel bell pushes are illustrated in a new leaflet from the General Electric Co., Ltd. (67 Queen Victoria Street, E.C.). Two of the prettiest ones have mounted on them little statuettes named Pierrot and Pierette.

**WATER HEATERS, BILLIARD IRONS, &c.**—New leaflets from Siemens Brothers Dynamo Works, Ltd. (Supplies Department, 38 and 39 Upper Thames Street, E.C.), draw attention to water heaters, saucepans, irons, &c., of similar design and construction to those shown in the general catalogue, except that the elements are easily renewable. In a new design of toaster the inside of the falling doors is fitted with nickel-plated rods so that the bread does not touch the doors, and moisture can readily escape.

**PLEXSIM COOKERS.**—A novel leaflet dealing with the advantages of Plexsim Cookers, as compared with the ordinary coal range, has just been got out by Simplex Conduits, Ltd. (116 Charing Cross Road, W.C.). Most of the matter is reproduced from a humorous article in a daily paper, and is embellished with a cleverly arranged folding picture. The leaflet is intended for contractors and central station engineers, and supplies may be obtained overprinted with their names and addresses.

**HEATING APPARATUS.**—A leaflet from the Sun Electrical Co. (118-120 Charing Cross Road, W.C.) describes a series of electrically heated boiling pots, jugs, &c., made of stoneware, which have recently been put on the market at very moderate prices. Another pamphlet deals with the "Rawlplug," already illustrated in our columns, for which the company are wholesale distributing agents.

### Scottish Local Section of the Institution of Electrical Engineers.

—A summer outing has been arranged at Inversnaid on June 17th. The party will leave Glasgow at 11.9 a.m. The inclusive price of tickets, including rail, steamer, lunch, &c., is 10s. 6d. By the courtesy of the Glasgow Corporation Water Department, those so desiring will be shown over the works at Loch Arklet.

**Annual Report of the I.E.E. Students' Section.**—The Report of the I.E.E. Students' Section for the session 1912-13 states that the average attendance at the eleven meetings held during the year was 36 with a maximum of 51. In Manchester there have been eight meetings, Glasgow five, and Newcastle nine. The average attendances were 38 in Manchester, and 15 in Glasgow. In London the average number of speakers was seven, and in Glasgow six. It is stated that arrangements are being made to hold a tour from July 2nd until July 5th, in the Newcastle district, and it is hoped that owing to its short duration the tour will be well supported. The Informal Electric Dinner recently held at The Tricity House was a great success, and it is hoped, states the report, to repeat such functions.

**An Astronomical Calculator.**—A convenient little piece of apparatus for enabling anyone to determine time, bearings, latitude, longitude, &c., by observations of the stars, has been devised by our friend, Mr. McBean, the less serious side of whose nature is well known to our readers from our cartoons. The appliance is published by George Philip and Son, Ltd. (32 Fleet Street, E.C.), under the name of the Boy Scout Astro-nomical Calculator, at the price of 6d., and consists of two card-board discs suitably graduated with scales of mean and sidereal time, latitude, the calendar, &c., and provided with convenient pivots and pointers. The arrangement is ingenious and very simple to use, and the apparatus has a considerable educative value in addition to its utility.

## REVIEWS OF BOOKS

- Electric Furnaces in the Iron and Steel Industry.** By W. Rodenhauser and I. Schoenawa. Translated by C. H. vom Baur. 419 pp. 9½ in. by 6 in. About 135 figures. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd.) 15s. net; abroad, 15s. 9d.

As indicated by the title, this treatise is devoted exclusively to electric furnaces for the iron and steel industry, and to the electro-metallurgy of the resulting products. The book, which is intended for the practical man, is divided into two parts, the first dealing with construction, and the second with the practical use of the furnaces. After a short historical introduction, some space is devoted to a consideration of electrical laws and phenomena in so far as they affect the operation of furnaces, which are then dealt with, first, generally, and secondly, specifically. In this connection those more extensively used, such as the Stassano, Héroult, Girod, Kjellin, and Röchling-Rodenhauser furnaces, are described in considerable detail, so that their behaviour, limitations, and most suitable applications, as compared with the ideal furnace, are brought out, and may be readily compared. The more important modifications of the above, together with proposed or little tried furnaces with possibly a future for certain classes of work, are briefly described in a chapter headed "General Review." Part I. concludes with a long list of the larger furnaces already in successful operation, and to which, no doubt, many more, it is to be hoped in this country, will have to be added shortly, now that electric power can be obtained at a very low price, and the products of the furnaces have been demonstrated to be of such very high quality. Part II. contains a quantity of very useful information, largely obtained from the personal experience of the authors, relating to the materials used in construction and the costs of operation for different purposes, together with some electro-metallurgy whereby the properties of materials made by different processes are rendered more easily intelligible.

- Theory and Calculation of Electric Currents.** By J. L. La Cour and O. S. Bragstad. Translated by S. P. Smith. 482 pp. 9 in. by 6¼ in.; 404 figures. (London: Longmans, Green and Co.) 16s. net; abroad, 17s.

It will be of advantage to those desiring to make a complete study of heavy electrical engineering to be able to purchase in one cover an exhaustive mathematical investigation into a multitude of the known phenomena of alternating currents. As a text-book, this work will appeal to some advanced students and others, but its sphere of usefulness is somewhat limited, though it should find a place on the shelves of most technical reference libraries. No fault can be found with the arrangement of the contents, nor the somewhat artificial treatment as a branch of mathematics, but it would have been an advantage to give a complete list of the symbols and signs used for easy reference. The subjects embraced include alternating currents and circuits and their representation, and the method chosen is the "symbolic" one, though vector diagrams are extensively used as well. Their effects in different practical installations is studied, and machines, measurements, the magnetic properties of iron, are treated, as well as electrostatics and its application in practice. For those not familiar with the symbolic method of representation of complex quantities, this is clearly outlined at the beginning of the volume. Unless one has a highly developed mathematical mind, however, the long expressions containing uncommon signs, with affixes, suffixes, dots below (which get mixed up with full-stops, &c.) and bars above, together with the more common conventions, will not prove as easily intelligible as they are to the authors. No very new or epoch-making result is arrived at, but some of the later chapters on dielectrics, transmission lines, and the capacity and conduction of cables, iron losses, and alternating-current instruments, are very useful and instructive.

**The Present Law and Practice Relating to Letters Patent for Inventions.** By H. Fletcher Moulton. 450 pp. 10½ in. by 6½ in. (London: Butterworth and Co.) 30s.; abroad, 31s. 4d.

Like other questions of law, those relating to Letters Patent daily become more involved, and since the passing into law of the Patents and Designs Act, 1907, many fresh questions have arisen on which enlightenment may be required by patentees and the many others interested in the ambit of patent specifications. The appearance, therefore, of this treatise, which deals with the law as it stood at the end of 1912, is to be welcomed, especially as it is very conveniently arranged and contains copious references to reported decisions in the various Courts where patent cases are heard, so that it is eminently suitable for quick reference. The matters dealt with include property in letters patent, novelty and subject-matter, public knowledge, sufficiency, disconformity, Patent Office practice and procedure, licenses, non-working, &c. The Act of 1907, and the copies of the forms on which applications, petitions, and other matters incidental to actions for infringement and similar cases, are also set forth. Stress is laid on the necessity for a clear and uniform system of drafting specifications, and some suggestions are given as to a suitable method to follow.

**Electricity and Its Practical Applications.** By Magnus MacLean. 492 pp. 9 in. by 6½ in.; 354 figures and 1 plate. (London: Blackie and Son, Ltd.) 10s. 6d. net; abroad, 11s. 10d.

The title of this work, as it appears on the title-page, indicates in a measure the nature of the contents. The word "electricity" is printed in large characters, and the continuation "and its practical applications" is added in smaller lettering. Thus the book treats mainly of electricity from an abstract point of view, while the real engineering applications take second place. The origin of the work explains the sharp line of demarcation between the two ingredients, which, although mixed up as regards position in the sequence of chapters, are distinct in style and treatment; almost as if two packs of cards had been shuffled together. The theoretical or historical—perhaps we had better call it *academical*—section is admittedly based on our dear old friend *Deschanel*, and bristles with the classic woodcuts of Faraday's net being turned inside out, Coulomb's torsion balance, Schweigger's multiplier, and other matters which used to delight our youth. The practical or engineering portion is adapted from that encyclopædic work, "Modern Electric Practice," of which, it will be remembered, Dr. Maclean was the general editor. Their origin and the reputation of the present author are guarantees that these constituents are both of excellent quality in their way, the treatment is sound and the style is readable; but what we miss are the connecting-links between the two. The student—and the book is really addressed to first-year students—will be liable to confuse the two parts. He will be inclined to think, for example, that a Bunsen battery is a practicable source of electric current, and will be inclined to call a Röntgen-ray tube an "electric egg." The historical order of development of a subject is not necessarily the most suitable logical sequence for the student to build up his knowledge of cause and effect. For example, the fact that some aspects of electrostatics were developed at an earlier period than the phenomena of currents is no reason why that part of the subject should be the best for the foundation on which the student is to build his ideas. There is, however, much that is excellent, and much that is admirably presented in the book, and here and there the old-fashioned nature of the treatment is a charm rather than a detraction.

**Single Phase Commutator Motors (Electric Mechanism, Part I.).** By F. Creedy. 113 pp. 8½ in. by 5½ in. 98 figures. (London: Constable & Co., Ltd.) 7s. 6d. net; abroad, 7s. 11d.

The author states that "the development of a new method of alternating-current analysis, independent of all others, with a suitable notation and conventions to accompany it, is no easy task, and has involved an amount of labour quite out of all proportion to the size of the volume." This is without doubt a fact, and advanced technical students and teachers will certainly revel in the new treatment presented, but how many professional designers will appreciate the efforts of the author is another matter. The treatment presented involves the abandonment of the phase diagram and the building up of a new vector diagram, in which the direction of the vectors represent directions in space and not in phase.

London: Crosby Lockwood & Son  
7, Stationers' Hall Court, E.C., & 5, Broadway, Westminster, S.W.

This necessitates the introduction of a large amount of co-ordinate geometry, especially of the ellipse, as this is in general, as is known, the distribution of flux and current in these machines. A further result is that the differences due to the various combinations of rotor and stator coils are brought out and readily compared. Whether, however, the method calls to mind any more clearly than the older methods the physical actions taking place is rather a matter for individual readers to decide. The method is certainly confusing at first, but might have been made clearer if a better system of diagrams had been used and if each diagram had been supplied with a short footnote.

**A Laboratory Manual of Alternating Currents.** By J. H. Morecroft. 247 pp. 9 in. by 5½ in.; 175 figures. (London: Longmans, Green and Co.) 7s. 6d. net; abroad, 8s. 2d.

The title of this book, which is of American origin, hardly does justice to its contents. Not only does it give in some detail instructions for carrying out series of tests, with diagrams of connections and particulars of the apparatus to be used, but a short and lucid discourse on the theoretical points of each test gives the reader an idea as to what results he should expect, and the accuracy which ought to be obtainable. The sequence of experiments is well chosen, so that the knowledge obtained from the earlier ones may be employed to advantage in those following. One of the benefits of this method of presentment is that the student has a considerable amount of thinking to do for himself, thereby gaining in self-reliance and initiative. Apart also from its value in the laboratory, this book should prove useful to a large number of students, not necessarily at technical colleges, who have a knowledge of D.C. work, and a fair knowledge of A.C. The behaviour of instruments and machines under divers practical conditions are set forth and explained in a clear and not too hypothetical way. To give an idea of the scope of the book, one may note that the experiments deal, amongst other matters, with wave forms and A.C. meters, and the accuracy of measurement; alternator regulation, efficiency and parallel working; transformers and phase transformation, &c.; synchronous motors, rotary-converters, induction motors and commutator motors, and the mercury arc rectifier. In addition there is an appendix dealing with the oscillograph and its many uses, while a large number of instructive photographic records are reproduced.

**Storage Batteries: The Chemistry and Physics of the Lead Accumulator.** By H. W. Morse. 266 pp. 7½ in. by 5 in.; 106 figures. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd.) 6s. 6d. net; abroad, 6s. 10d.

Much useful information for both the student and practical man is contained in this conveniently arranged work. Seeing that there are numbers of men who should, but who do not, know very much about the physics and chemistry of the storage cell, it is gratifying to be able to welcome this contribution to the rather meagre literature on the subject. The author does not indulge in some of the more speculative theories as to the exact quantity or quality of unstable compounds which may be formed, but of whose presence the evidence is more or less circumstantial, but in an easy and convincing style presents a theory which fits well with established facts, though it may be amplified if necessary. Towards the end of the book a quantity of information on the physical characteristics of different cells as influenced by all the factors obtaining in practice is clearly set forth. The different kinds of plates, their formation and the best fields for their application, are given, as well as the manufacturing tendencies in different parts of the world for different services. Although the chemistry and physics of the Edison or iron/potassium hydroxide/nickel peroxide cell have not yet been thoroughly investigated, some interesting comparative notes are included.

**Manual of Wireless Telegraphy and Telephony.** By A. F. Collins. 300 pp. 7½ in. by 5 in.; 129 figures. (New York: John Wiley and Sons; London: Chapman and Hall, Ltd.) 3rd edition. 6s. 6d. net; abroad, 7s.

This book is addressed principally to wireless telegraph operators and those about to take up this class of work. Although of American origin, and therefore dealing here and there with apparatus, methods, and even codes, more used in the United States than in other parts of the world, there is much to make it of interest to all who desire more really practical information than is to be found either in the scientific treatises or semi-popular handbooks that abound on both

## BLACKIE'S LIST

### ELECTRICITY & its Practical Applications.

By MAGNUS MACLEAN, D.Sc., M.Inst.C.E., M.I.E.E., Professor of Electrical Engineering, Royal Technical College, Glasgow. Demy 8vo. 10s. 6d. A new work for engineers and science students.

### ELEMENTARY PRINCIPLES OF ALTERNATING CURRENT DYNAMO DESIGN.

By A. G. ELLIS, A.C.G.I., A.M.I.E.E. Demy 8vo. 12s. net.

"A most reliable, up-to-date, and satisfactory treatise. The author is to be congratulated upon his method of treatment."—*Electricity*.

### ELECTRICAL ENGINEERING MEASURING INSTRUMENTS.

For Commercial and Laboratory Purposes. By G. D. ASPINALL PARR, M.Inst.E.E., Head of the Electrical Engineering Department, University of Leeds. A fully illustrated, classified, descriptive, and technical account of the many available measuring instruments. Demy 8vo, 9s. net.

"We can heartily commend this work."—*Electricity*.

## BLACKIE & SON LIMITED

50, OLD BAILEY, LONDON, E.C.

sides of the Atlantic. The general principles are explained with admirable clearness by the study of a simple experimental set, and the elaboration in actual commercial apparatus of greater range are subsequently gone into in considerable detail. The hints on adjusting and operating the instruments should be found most useful, and throughout the work care has been taken to avoid confining the particulars to any one system, so that the student should not be strange to the functions of the widely differing component parts of any commercial equipment which he may have to take charge of. There is, perhaps, more diversity of apparatus in use in America than here, and this characteristic has ensured a broader treatment than might otherwise have been adopted. It should be remarked, however, that some of the descriptions of commercial sets are not quite up-to-date. A short final chapter on wireless telephony, by Mr. Newton Harrison, describes the Collins arc method, which appears to have made more progress than is realised over here, and an excellent bibliography and a glossary complete the book.

**Introductory Electricity and Magnetism.** By C. W. Hansel. 373 pp. 7½ in. by 5 in.; 283 figures. (London: W. Heinemann.) 2s. 6d. net; by post, 2s. 10d.

The author has managed to cram a large amount of good matter between the two covers of this conveniently-sized manual, which is divided into three sections, as follows: magnetism, electrostatics, and current electricity; but over half of the available space is devoted to the last. The subject is developed experimentally, and the earlier chapters in each section deal with qualitative phenomena, while the later chapters are quantitative in character and naturally more advanced. In this connection it may be said that the reasoning is clear and concise, and the remarks are qualified by reference to surrounding conditions. The chapters in each section contain useful information, both practical and theoretical in character, and the experiments have been well chosen, and in most cases can be performed with simple apparatus. The large number of diagrams are clear, but somewhat crude. Although there are many similar books available, this one may be thoroughly recommended to those preparing for elementary examinations in electricity and magnetism.

**Bells, Indicators, Telephones, Fire and Burglar Alarms, &c.**

By J. B. Redfern and J. Savin. (Electrical Installation Manual.) 123 pp. 6½ in. by 4½ in.; 85 figures. (London: Constable and Co., Ltd.) 1s. 6d. net; by post, 1s. 7½d.

The wireman whose work is mainly electric light and power wiring frequently feels that he is on somewhat uncertain ground when called upon to carry out even comparatively simple bell and telephone installations. To this class of worker this small and unambitious volume will be of great utility. It is clearly written, and judicious use is made of the limited space at the disposal of the authors.

**Descrizione di una Macchinetta Elettro-magnetica.** Del Dr. A. Pacinotti (Associazione Elettrotecnica Italiana).

The happy thought occurred to the Italian Electrotechnical Association of publishing in book form a reprint of the original article by Dr. Antonio Pacinotti, written in June, 1864, and published in the *Nuovo Cimento*, together with translations into other languages by eminent writers. The original Italian text is preceded by an excellent photogravure portrait of Pacinotti, and is followed by a translation into French by Paul Janet, a translation into English by Silvanus P. Thompson, translation into German by Gisbert Kapp, and a translation into Latin by P. Rosi. The important historical position taken by Pacinotti's work is not as fully realised as it ought to be, and we hope that the publication of this little book may help to make it better appreciated.

**Methods of Measuring Electrical Resistance.** By E. F. Northrup. 389 pp. 9½ in. by 6½ in. 158 figures. (New York: McGraw-Hill Book Co.) 17s. net.

Every student of electrical engineering must learn how to measure electrical resistance. The acquisition of this knowledge, however, represents but a small portion of his complete training in elementary electrical matters, and he can hardly be expected to tackle or to pay for a book of 389 pages, and costing 17s., devoted to this subject alone. On the same scale, a complete library for an electrical student would fill a house, and cost a little fortune, and by the time he had diligently read it through he would have reached the age at which most men retire from business. The great length of this volume, however, is not so much due to the amount of matter given to the reader for assimilation as to the large number of words employed to wrap the matter up, and we cannot regard the persistent abbreviation of the word through to "thru" as any compensation for this. It is evident that the author possesses a considerable amount of knowledge and experience of the subject upon which he writes, and it is to be regretted that the form in which he presents it in his book is not likely to prove attractive either to the student or to the busy man engaged in actual practical work.

**Psychology and Industrial Efficiency.** By H. Münsterberg. 321 pp. 8½ in. by 5½ in. (London: Constable & Co., Ltd.) 6s. net; abroad, 6s. 5d.

To use the author's own words, his aim is to sketch the outlines of a new science intermediate between the modern laboratory psychology and the problems of economics—psychological experiment systematically placed at the service of commerce and industry. The methods suggested, some of which have actually been used and have been found to give correct results, are extremely interesting and worthy of careful study by those who have the control of large industrial undertakings. Moreover, the author is an authority in this comparatively new subject, and his book is fascinating reading even for those to whom it may not be of actual practical service. Among the illustrations given is a test worked out for some tramway undertakings in the United States to predetermine the suitability and adaptability of candidates for motormen's duties; another is a series of tests to aid in the selection of telephone operators. In addition to the chapters on "The Best Possible Man," there are others on "The Best Possible Work," the most interesting and suggestive of which is on "The Economy of Movement," and "The Best Possible Effect," which, however, seems rather more academic and less convincing.

**Electricity made Plain.** By G. R. Peers. 133 pp. 7½ in. by 4½ in. 54 figures. (Manchester: John Heywood, Ltd.) 1s. net; by post, 1s. 3d.

It is difficult to see what useful purpose this little publication is intended to serve. It is supposed "to explain the various and many uses of Practical Electricity in a general way sufficiently intelligible to the average reader without scientific knowledge." A large number of the applications of electricity are touched on in a scrappy way, and where engineering terms are introduced they are either not explained or else the explanation is inadequate; in some cases, too, the reasoning is weak. Nearly all the illustrations used are culled from manufacturers' catalogues, and the too large proportion of the book devoted to medical electricity reads in places like an advertisement for beauty parlours and similar institutions. Unfortunately, too, the author makes the grievous mistake of dismissing electric heating and cooking in less than a page, as he says its expense is too great.

**Iron and Steel.** By O. F. Hudson, with a Section on Corrosion by G. D. Bengough. 173 pp. 9 in. by 5½ in. 47 figures. (London: Constable & Co., Ltd.) 6s. net, abroad 6s. 6d.

The constitution of steel and cast-iron and the effects of heat treatment on their properties are fully discussed in the light of the latest researches and theories. The letter-press is embellished with a large number of clear micro-photographs of the construction of the different alloys. A valuable chapter is that devoted to the iron carbon alloys from the consideration of alloys being composed of pure metals, compounds either of metals with non-metals or metals with metals, and solid solutions. "Equilibrium diagrams" are given. Practical details of the methods of production are not considered—electrical furnaces are dismissed in a few lines. The chapter on corrosion, like the other parts of the work, embodies the results of recent investigations and sets forth the most feasible theories as to the actions taking place in a straightforward manner. From a study of these actions, preventive courses may be adopted.

**Worm Gearing.** By H. K. Thomas. 86 pp. 9½ in. by 6½ in. 33 figures. (New York: McGraw-Hill Book Co.; London: Hill Publishing Co.) 6s. 3d.

In view of the high efficiency which this form of transmission gear has now reached, and its rapidly extending use, the issue of the book is well timed. The theory of worm-gear is dealt with in a clear and simple manner, without the use of complicated mathematics. The recent interesting tests of the Lanchester gear by the National Physical Laboratory are only referred to in a footnote, otherwise the book appears to contain all that may be expected of it from its title. Choice of material and methods of manufacture receive due attention, and the simple formulae for use in practical designing will be found useful. The differences between the Lanchester or "diabolo" form of worm and the straight worm are discussed, and on this question we may quote Mr. Thomas, as follows:—"It may be observed that in the case of a straight worm . . . a double thrust bearing should be provided at one end, the other can then be left free to expand or contract with the differences of temperature which occur when running. In the case of the hour-glass pattern worm, it is difficult to say what happens when it has to expand; presumably the casing expands too, and in that case a single thrust bearing at either end is the better arrangement." All this goes to show that the author, in specialising on worm gear, has brought much common sense to bear on the subject.

**The Motor Manual.** 266 pp. 7½ in. by 5½ in. About 245 figures. (London: Temple Press, Ltd.) 16th edition. 1s. 6d. net; by post, 1s. 9d.

The sixteenth edition of this deservedly popular manual has been to a large extent re-written and re-illustrated, and is thoroughly up to date in all matters of detail. The space given to the magneto in the ignition section has been enlarged, as that form of ignition is now becoming practically universal. The information regarding the care and charging of accumulators is very practical, and a section is included on car-lighting dynamos, but on account of the comparative novelty of the subject this is not treated with quite the degree of detail as characterises the rest of this excellent little work, nor do we find any reference to electrical engine starters.

**ELEMENTS OF ELECTRICAL ENGINEERING.**

Edited by J. L. LA COUR, Technical Manager, Allmanna, Svenska Electrical Co., Sweden.

JUST PUBLISHED. 16s. net.

**THEORY AND CALCULATION OF ELECTRIC CURRENTS.**

By J. L. LA COUR, Vesteras, and O. S. BRAGSTAD, Trondhjem.

Translated by STANLEY P. SMITH, D.Sc., Assoc. M.Inst.C.E., &c. With Diagrams. 8vo.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,337.

**Coal Mines Act Electrical Rules:**—Rule 14, C (1), requires "the thorough examination of all apparatus (including the testing of earth conductors and metallic coverings for continuity) as often as may be necessary to prevent danger; and (2) the examination and testing of all new apparatus, and of all apparatus re-erected in a new position in the mine before it is put into service in the new position." Under ordinary circumstances how often will it be advisable to test earth conductors and metallic coverings, and what other "examination and testing" is necessary on the following plant? How may we prove that we have continuity and suitable carrying capacity of all armour and earth conductors? We have two 2,000-kw. generators, 3,000 volts, 40 cycles, three phase; current is transmitted at this pressure to three seams at different depths. In these seams we have haulages working direct at 3,000 volts; also in each seam we have transformers stepping down to 440 volts for pump motors and small haulage, and small lighting transformers 440 to 110 volts. The cable from the H.T. switch-board in the power-house to each seam is three-core, paper-insulated, lead-sheathed, and double-wire-armoured; it is fixed to sides of shafts by wooden cleats, and the shaft is comparatively wet. We use the lead sheath and armour as our main earth connection to surface earth plate. The shaft cable is led to a distribution board in each seam, from which all cables in use are also double-wire armoured, and the armour in every case is used as main earth wire between each motor, &c., and main cable armour to surface. I may mention here that in some places the cables are buried in the ground. We have two C.I. earth plates at the surface, and one in the sump at each seam. We transmit about 600 kw. into each seam. The depths of the seams below surface are 400 yards, 500 yards, and 680 yards. At each motor we connect up the switch, controller, motor frame, &c., to a common copper earth wire, and this to armouring of cable by means of W.I. clamps, as, of course, we cannot solder terminals on here underground.

"ASSISTANT ELECTRICIAN."

(Replies must be received not later than first post, May 29th.)

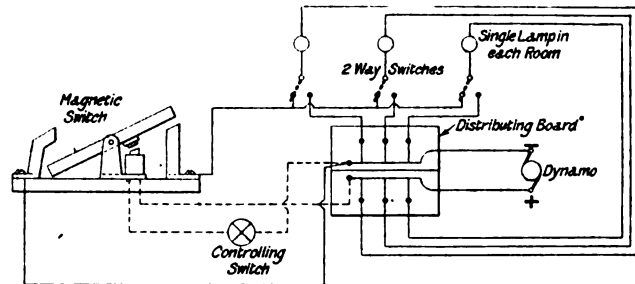

## CORRESPONDENCE

### BURGLAR ALARMS.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—With reference to the letter addressed to you in connection with the diagram I submitted to you re burglar alarms, I would thank your correspondent Mr. C. W. Von Roemer for calling attention to an error which I made in the diagram. Instead of single-pole switches being shown, these should have been ordinary two-way switches, the common terminal being connected to the lamps, the two switch points being connected to the distribution board and the common terminal of the magnetic switch respectively. This obviates the necessity of numerous contact arms on the magnetic switch. I enclose a

further diagram for reproduction if you consider it necessary for making the matter quite clear. In working, the two-way switches would permanently keep the burglar lamps connected to the magnetic switch, so that when occasion arose for the control

switch to be turned on these lamps would immediately light. So long, however, as the control switch remained off, each of these burglar lamps could be worked independently by means of the two-way switch.

ALARM.

May 13th, 1913.

### A SPRING CLIP GALLERY

THE ordinary carrier-ring method of attaching shades to lamp holders has had a long and evil reign, and has been responsible for much inconvenience. Even with thumb-screw galleries there is a risk of gripping the glass too tightly, or of getting the shade out of centre. The B.T.H. spring-clip gallery, for use with Veluria, Opalux, Holophane, or any other standard types of reflectors, is a great improvement. It is provided with a spring-clip consisting of a wire ring attached to the interior circumference, which enables the reflector to be securely fixed in a few seconds. This ring

B.T.H. SPRING CLIP SHADE GALLERY, SHOWING METHOD OF ATTACHING THE SHADE.

can be expanded or contracted by means of a lever. To attach a reflector it is only necessary to place the neck inside the gallery and to contract the spring-clip over it by pushing the lever with the thumb. This method of attachment is not only secure and quick and positive in action, but it is impossible for the reflector to be gripped too tightly, or to be out of correct focus with the lamp. Again, the flexible spring-clip allows for the expansion of the glass. These galleries are made of stamped brass, and can be supplied in various finishes. They are made in two neck diameters and in three depths.

**Yorkshire Local Section of the Institution of Electrical Engineers.**—At the annual general meeting of the Yorkshire Local Section of the Institution of Electrical Engineers, held at Leeds last week, the following officers were elected:—*Chairman:* Mr. W. B. Woodhouse (Chief Engineer, Yorkshire Electric Power Co.). *Vice-Chairmen:* Mr. H. H. Wright and Dr. R. Pohl (Phoenix Dynamo and Motor Co.). *Hon. Sec.:* Mr. J. D. Bailie (C. A. Parsons & Co.). For the four vacancies on the Committee, Messrs. W. M. Rogerson (Borough Electrical Engineer, Halifax), H. A. Nevill (Electrical Engineer to the Corporation of Wakefield), W. Lang (Callendar's Cable & Construction Co.), and F. J. Lowe were elected to take the places of Messrs. Barker, Bailie, Pohl, and Wilkinson, who retire by rotation from the Committee.

## "ELECTRICAL ENGINEERING" PATENT RECORD

*(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)*

### Specifications Published May 15, 1913

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications. Names in italics indicate communicators of inventions from abroad.

9,416/12. **Petrol-electric Traction.** H. LEITNER. In this system the engine drives a generator with two commutators, one of which supplies the power current at a variable voltage, while the other provides the excitation. This is varied by shifting auxiliary brushes. A separate constant voltage variable-speed generator is also provided for the lighting and other auxiliary services. Four figures.

9,513/12. **Heating Apparatus.** J. C. P. KIRKWOOD. The heat is regulated by an automatic regulator actuated by the differential expansion of dissimilar metals, which cuts out sections of the heating element as the temperature rises. Two figures.

13,455/12. **Plug Switches.** A. WYNNE. A switch inside the socket is operated by the insertion and withdrawal of a wall plug, which carries an extra plunger for the purpose. It is so arranged that the switch is not closed till the plug contacts are well home, but is opened (with a quick break action) well before they are fully withdrawn. Two figures.

19,792/12. **Air Filter.** G. A. MOWER and K. O. HALE. The ventilating air for turbo-generators, &c., is passed through a washer containing numerous spraying nozzles and eliminating plates to prevent spray being carried over by the air. Three figures.

20,663/12. **Fuses.** B.T.-H. Co. (*G.E. Co., U.S.A.*). These fuses are for low-current circuits, and consist of pads of yielding refractory material with a number of fusible rods or threads passing through them, arranged in various ways, sometimes in conjunction with blocks of carborundum or other material of negative temperature coefficient of resistance, which vary the proportion of the current passing through the fuse according to its magnitude. Three figures.

20,828/12. **Commutators.** W. H. SCOTT. A method of constructing radial commutators with the segments held by an external band and an inner ring expanded by force from inside. Two figures.

25,104/12. **Electric Heating System.** H. LOFQUIST. A heating system for houses in which electrically heated water circulates in pipes, and a combined switch controls the circulating pump motor and the heating elements. Three figures.

26,289/12. **Metal Filaments.** WESTINGHOUSE METALFADEN GLUHLAMPENFABRIK. Metal filaments of great length are made compact by forming into a helix prevented from liability to stretching by the inside diameter of the helix being not greater than the diameter of the filament.

### Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, E.C., at the price of 8d. each, post free. Summaries of some of the more important of these patents will appear in our next issue.

**Arc Lamps:** B.T.-H. Co. (*G.E. Co.*) [Electrodes] 18,689/12; KÖRTING & MATHIESEN [Blow magnet] 318/13.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** MEIROWSKY [Insulators] 13,365/12; W. E. Co. (*W. E. Co., U.S.A.*) [Cable sheath] 16,153/12; B.T.-H. Co. (*G. E. Co., U.S.A.*) [Protective gear] 17,680/12.

**Dynamos, Motors, and Transformers:** BROWN, BOVERI [*A.C.*] 7,258/12; PODLESÁK [Magneto] 10,209/12; SUBMERSIBLE AND J.-L. MOTORS and COOPER [Motors] 10,654/12; SUBMERSIBLE AND J.-L. MOTORS and POYNTER [Dynamos] 10,655/12; HILDEBRAND [*D.C.-A.C. transformation*] 17,346/12.

**Heating:** MARKS (*Landers, Frary and Clark*) 10,029/12; [Elements] 24,776/12; E. & O. ACCESSORIES Co., MORRISON and DAVIES [Elements] 10,765/12; MANN [Water-heater] 11,849/12.

**Ignition:** PODLESÁK, 25,646/12.

**Incandescent Lamps:** HANSEN and MOHR [Filament manufacture] 9,941/12; GALLAY [Lamps for automobiles] 27,785/12.

**Instruments:** ARON [Electrical regulation of clocks, &c.] 23,590/12.

**Storage Batteries:** HEIL [Electrodes for primary and secondary batteries] 10,541/12.

**Switchgear, Fuses, and Fittings:** MOLLETT and EDWARDS [Shade supports and lamplocks] 10,753/12; SCHOLÉS [Adjustable pendants] 10,780/12; NALDER BROS. & THOMPSON and HARRIS [Switches] 11,260/12; WILLIAMSON [Portable light fittings] 13,152/12; SIEMENS DYNAMO WORKS and PAYNE [Controllers] 16,343/12; JOHNSON [Regulating devices for lamps] 22,127/12; SCHEINIG [Wall-plugs] 23,588/12; GLENN and BRITISH PNEU-

MATIC RAILWAY SIGNAL Co. [Protective motor switch] 3,446/13; B.T.-H. Co. and BRITTON [Motor controller] 4,093/13; BERGMANN [Reversing polyphase commutator motors] 4,691/13; JOEL [Portable battery lamps] 5,073/13.

**Telephony and Telegraphy:** HACKING [Signalling systems] 27,974/11; GODFREE [Automatic telephone toll recorder] 7,264/12; BECKER [Regulating attenuation on Pulin lines for different frequencies] 7,903/12; HUERTLEY [Telegraphy] 9,733/12; AUTOMATIC TELEPHONE MFG. Co. (*Automatic Electric Co.*) [Impulse transmitters] 10,120/12; TELEPHONFABRIK A.-G. [Branch exchange telephone systems] 10,364/12; MARTIN [Telephone systems] 10,376/12; GALLETT [New wireless system] 10,863/12; AUTOMATIC TELEPHONE MFG. Co., AITKEN, COOPER and REMINGTON [Intercommunicating telephones] 13,963/12; DUBILIER [Wireless] 14,015/12; GOLDSCHMIDT [Reception of wireless waves] 23,734/12; GRISSINGER [Telephonic transmitters] 2,928/13.

**Traction:** BLACKALL and JACOBS [Railway signalling] 17,035/12; EDDON [Simultaneously locking and unlocking railway carriage doors] 24,893/12.

**Miscellaneous:** SUBMERSIBLE AND J.-L. MOTORS and POYNTER [Pumping] 10,653/12; WESTINGHOUSE LEBLANC [Balancing rotating masses] 16,809/12; BRYDONE [Theft alarm boxes] 27,002/12; YARROW [Synchronising for coupling rotating shafts] 27,095/12; ACHENBACH [Primary batteries] 29,847/12.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Dynamos:** MASON 8,128/13.

**Electrochemistry:** LAFFITTEAU [Liquid sterilisation by ozone and ultra-violet light] 9,281/13; [Liquid sterilisation by ozone] 9,282/13.

**Ignition:** MASON 4,670/13.

**Meters:** A. E. G. [Ampere-hour meter] 9,503/13.

**Switchgear, Fuses and Fittings:** Soc. L. ELÉRIOT [Switchgear and switch contacts] 9,592/13.

**Telephony:** STILLE [Telephonic reproducers] 9,644/13.

**Traction:** CASTELLETTI [Electric vehicle brakes] 9,274/13.

**Miscellaneous:** KRUPP [Alarm signal for ordnance] 5,872/13; STILLE [Aluminium-acetone light sensitive cells] 9,060/13 and 9,061/13.

### Application for Amendment

22,342/04. **Arc Lamp Carbons.** KÖRTING & MATHIESEN A.-G. This patent covers a method of ensuring good contact between a metallic core and the surrounding carbon by giving the wire a corrugated form before it is drawn in. The desired amendments include six verbal alterations, having the object of limiting the scope of the claims.

### Grant of Patent Allowed

2,325/12. **Automatic Railways.** J. J. DESCHAMPS. The Comptroller has allowed the grant of this patent in spite of opposition. The system in question is for driverless goods trains. The starting resistances are external to the cars, and are connected to sections of the conductor rail, and an arrangement of automatic points is provided for to shunt cars into sidings where they are automatically stopped.

### Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

**Dynamos, Motors, and Transformers:** B.T.-H. Co. (*G.E. Co., U.S.A.*) [Single-phase motors] 1,670/05; A.E.G. [Single-phase motors] 99/07.

**Heating and Cooking:** H. J. YATES and D. R. MCNEIL [Doors and shelves for electric stoves] 2,343/02.

**Ignition:** E.I.C. and F. H. HALL [Distributors] 1,984/08.

**Incandescent Lamps:** H. ZERNING [Carbon filaments coated with metals or carbides] 2,437/06.

**Instruments and Meters:** H. ARON [Details of meters] 2,466 and 2,467/04; F. J. BEAUMONT [Slot meters] 1,959/08.

**Switchgear, Fuses and Fittings:** R. W. BROWN [Motor starting switches] 2,067/05.

**Telephony and Telegraphy:** E. E. CLEMENT [Coherer call system] 2,598/03.

**Traction:** H. J. JEFFCOATE [Railway cab signalling] 2,109/02; E. A. MITCHELL [Surface contact slides] 11,945/08.

**Miscellaneous:** PHYSIKALISCH-TECHNISCHES LABORATORIUM GES. [Ballast resistances] 2,641/06; I. H. SPENCER [Vacuum cleaners] 2,478/07; G. H. RAYNER and C. WALTON [Rock drills] 2,201/08.

# ADAMS IGRANIC

MOTOR CONTROL GEAR FOR MACHINE TOOLS.

ADAMS  
MFG CO LTD  
BEDFORD  
AND  
LONDON

## A LIFT CONTROLLER

WE illustrate here a new design of controller for small electric hoists and lifts which has just been brought out by the Adams Manufacturing Co. (Balfour House, Finsbury Pavement, E.C.). This lift controller is arranged for rope operation, the pulley for the rope being mounted on the spindle projecting from the top of the apparatus. It consists essentially of a box containing the necessary starting resistance. On the front of the box is mounted one of the new "Z"-type automatic starters, which consists of a number of contact fingers which are brought into operation by the solenoid, and so arranged that the motor starting resistance is gradually short-circuited and the motor brought up to speed, and an adjustable dashpot controls the rate at which this part of the apparatus works. On top of the box is mounted a drum-type reversing switch, which, by the operation of the rope, makes the circuits for the motor to revolve in the required direction, and then energises the solenoid on the "Z"-type starter. It will be seen that the controller is simple and robust, which should go far towards ensuring its reliability.

ADAMS LIFT CONTROLLER FOR ROPE CONTROL.

## CATHEDRAL LIGHTING

WE give here, through the kindness of the General Electric Co., Ltd., an interior view of the choir of York Minster, which has recently been provided with an installation of Osram lamps. The way the lamps are arranged

CHOIR OF YORK MINSTER, SHOWING ELECTRIC LIGHTING ARRANGEMENTS.

shows up the beauty of the carving and tracery to its very best advantage, and the adoption of electric lighting will preserve the fabric of the Cathedral from deterioration caused by the deposits formed by other illuminants.

## ELECTRIC TRACTION NOTES

A further conference has been held between the Postmaster-General and the Tramways and Light Railways Association and the Municipal Tramways Association on the question of guard-wires. The first point raised, says the official circular of the Tramways and Light Railways Association, was that in cases where the Post Office is the second comer the Post Office should pay the whole cost of the guard-wires instead of one half, as at present. The Postmaster-General refused to accept this proposition, and added that if the question is to be reopened he should decline to bear any part of the cost even in "second-comer" cases. The Postmaster-General further refused to consider the suggestion that each party should pay one half of the cost of removing the existing guard-wires and substituting the necessary protection afforded by the use of insulated wires. He agreed that guard-wires might be removed after application to him and at the expense of the tramways undertaking, on the understanding that the Post Office engineers should be employed for removing or insulating the bare wires, the cost to the tramways company being at the rate of 5s. 9d. per wire, or 11s. 6d. per circuit.

The overhead equipment of the Turin-Modane section of the Italian State Railway system is now being erected. The three-phase locomotives to be run on this section are constructed for a 25-cycle supply, and as the available power is at 50 cycles, transformer stations with frequency-changing sets are being installed. These machines will be provided with heavy flywheels with the object of reducing the peak loads on the generating station.

The Hong Kong Tramway Co., which was started in 1902, is able for the first time to pay a dividend on its ordinary shares for last year. This is at the rate of 7½ per cent.

It is stated that Messrs. Griffiths and Co. of London are negotiating with the New South Wales Government with regard to the financing and construction of an underground railway system in North Sydney.

The Hagley Road tramway of the Birmingham Corporation, which has been strongly opposed by the frontagers ever since the line was first promoted, is now completed, but the opposition still continues, and is taking the form of a request for single-deck cars which is thought will reduce the dust nuisance, and also the running of "first-class" cars similar to those now in use in Liverpool.

A sum of £56,352 is to be transferred to relief of rates by the Birmingham Corporation Tramways Department.

A bill providing a sum of £1,600,000 for the electrification of the St. Petersburg suburban railways has been introduced into the Duma.

The sub-committee recently appointed to inquire into the working of the Lowestoft Corporation tramway system has reported against the selling or leasing of the undertaking. They are of opinion, however, that the charge for current is excessive, and suggest that the Electric Lighting Committee should reduce it to 1½d. per unit. The installation of meters on the cars is also recommended with a view to reducing the consumption of current, and it is also suggested that a bonus of 10 per cent. be paid to motor-men and conductors when the month's takings exceed the maximum amount previously taken in any month.

The London County Council has, it is announced, been experimenting successfully with Stevens petrol-electric tram-cars on the South Hackney and West India Dock routes. It is expected that the Highways Committee will return to the subject at the next Council meeting.

The agreement between the Manchester Electricity and Tramway Committees, referred to in our last issue, is for 30,000,000, and not for 3,000,000 units per annum as we erroneously stated.

We understand that Lord Bessborough, Chairman of the London Brighton & South Coast Railway, has just returned from a trip to Germany, where he has been inspecting electric railway systems.

### TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

A new telephone cable is to be laid shortly between Marseilles and Algiers. The core will consist, according to the *Annales des Postes, Télégraphes et Téléphones*, of seven copper strands, each 0.8 mm. in diameter, with three layers of gutta percha, weighing in all 52 kg. per (nautical) mile. The resistance will be 9.2 ohms and the capacity 0.35 m.f. per mile, and the insulation resistance 300 megohms per mile. The armouring of the deep-sea portion will consist of sixteen 2.5 mm. steel wires, that of the intermediate cable twelve 4.5 mm. steel wires, that of the coast section ten 7 mm. steel wires, and that of the shore end, twelve 4 mm. steel wires. The cable will be laid with 4 to 8 per cent. slack.

The United River Plate Telephone Co. has made a profit of £105,082 on the year. A dividend of 8 per cent. is recommended, and to provide for the growth of business a new issue of 54,000 ordinary shares will be offered to existing shareholders at £5 10s. per share.

In connection with the reception of messages up to 2,400 miles from the Fort Meyer wireless station at Arlington, by the U.S. scout *Salem*, reported in our columns, March 27th, p. 179, it is interesting to note in the *Electrical World* (New York) that the equipment of the *Salem* consists of the usual type of antenna 160 ft. long and 40 ft. in width. The sending equipment consists of a 10-kw. motor-generator feeding a transformer at 500 cycles, which steps the pressure up to 12,500 volts. Compressed air condensers and synchronous rotary spark gaps similar to those in use at Arlington (*ELECTRICAL ENGINEERING*, February 27th, p. 120) are used. The receiving circuit contains Fessenden liquid barratter and Nexon crystal detectors. In addition, the heterodyne receiver was used when the signals were faint or when interference from other stations was necessary. Its action depends on the interaction of two persistent high-frequency currents—one local and the other set up by the received wave energy—to produce an amplified audible or other response. This device has now been developed

to the point at which it is said to give increased indications over those normally had on the receipt of fairly well sustained waves, yet, because of its requirement of a considerable degree of persistence for amplification, it does not add to the false signals produced by highly damped atmospheric disturbances. Messages were sent in daylight from the *Salem*, and received at Arlington by two operators simultaneously over a distance of 1,300 miles. The *Salem* was also able, while at Gibraltar, to receive messages at night from Arlington.

The April issue of the *Telefunken Zeitung*, of which Siemens Brothers and Co., Ltd. (Woolwich), have just sent us a copy, opens with an obituary of Prof. Slaby from the pen of Count Arco, and announces that for the first time, at the end of January last, experimental communication was established between Nauen (near Berlin) and New York, a distance of nearly 4,050 miles. Several interesting equipments in various parts of the world are described, and a map is given showing the thirty-three stations which are to be established round the German coasts and frontiers for airships to be able to find their bearings by the "Telefunken Compass." Several wireless telegraph equipments used in the Balkan war are also illustrated.

The rapid progress of wireless telegraphy in Australia is shown by an official communication just issued by the High Commissioners. Of the £50,000 voted for the construction of a chain of wireless stations during the financial year ending June 30th, 1913, £40,000 has already been expended, and stations are now transacting business at Melbourne, Sydney, Fremantle, Adelaide, Hobart, Brisbane, Thursday Island, and Port Moresby. Other stations are practically finished at Cooktown, Rockhampton, Mount Gambier, Geraldton and Esperance, whilst there are still others in course of construction at Roebourne, Wyndham and Broome, and also Port Darwin.

We learn that telegrams to Honduras and Salvador are no longer subject to censorship, and that on the 16th inst. the cable between Madagascar and La Reunion was restored.—The Persian land-lines between Barfrouch and Mechedeser were down on the 17th inst. to 19th inst., and lines in Angola were down on the 18th inst. to Avillengues and Caconda.—The lines between Alep, Bagdad and Diabekir were down on the 19th inst.

## LOCAL NOTES

**Devonport: Electricity Profits.**—There was a net profit of £390 on the working of the electricity undertaking last year, and the whole of this sum is to be placed to reserve fund, which will now stand at £8,274. The coal bill for the year, due entirely to increased prices, was £1,200 more than in the previous twelve months.

**Dover: Electricity Accounts.**—There was a debit balance of £861 on the electricity undertaking last year.

**Supply to St. Margaret's.**—The Board of Trade has sanctioned a supply of electricity being given here by means of overhead cables.

**Gravesend: Rateable Value System of Charging.**—The Borough Electrical Engineer has recommended as an alternative tariff the rateable value system on the basis of 15 per cent. of the net assessable value per annum payable quarterly in advance, plus 3d. per unit for all current consumed.

**Hebburn: Safety of Electric Cables.**—As a consequence of the mysterious explosion, which occurred on March 30th, and which caused the death of two persons (ELECTRICAL ENGINEERING, April 24th, p. 228), the Council has asked the Board of Trade to hold an inquiry into the matter with a view to ascertaining whether any further steps are necessary to be taken to ensure the safety of the public. In the meantime an application by the Northern Counties Electric Supply Co. to lay further high-tension cables in the town has been disapproved of unless the cables are laid in earthenware troughs.

**Ipswich: Electricity Accounts.**—There was a loss of £1,708 upon last year's working of the electricity undertaking. After drawing this amount from the reserve fund, the balance to the credit of the latter is £815. The principal causes which have led to this result are the increase in the cost of coal, heavy capital charges on additional plant which is not at present earning revenue, and the large charge on revenue to cover the wages of permanent employees engaged on work of a capital nature necessitated by the policy of the Local Government Board. In the course of his report, Mr. F. Ayton, the Chief Engineer and Manager of the undertaking, calls attention to the desirability of offering every inducement for the use of electric vehicles in Ipswich now that the Edison battery is being introduced into this country on a commercial scale. The Council is also urged to introduce the hiring of electric cooking and heating apparatus. During the year a further fifty street gas lamps were changed over to electric, bringing the total number of public street electric lamps to 124.

**Leeds: Electric Lighting Accounts.**—The electric lighting undertaking for the past year has again developed at a rate greater than in any preceding period. As the result of reductions in price the revenue from private lighting is £1,747 less than in the preceding year, but the number of consumers has increased from 7,165 to 8,101. The total revenue, however, has increased by £9,751, and the net profit is £15,508 compared with £16,065 in the previous twelve months. This reduction, however, is more than accounted for by an increase of £1,885 in the amount expended out of revenue upon permanent works.

**Norwich: New Plant.**—An official inspection has taken place of the new turbo-alternator and coal-conveying plant, and an opportunity was taken at the same time of holding an exhibition of cooking appliances.

**Nottingham: Electro-Medical Hospital.**—An electro-medical hospital was opened last week, when addresses were delivered by Sir Lancelot Rolleston and Dr. F. H. Humphris, two of the leading authorities on electro-therapeutics.

**Radcliffe: Free Electricity.**—It is stated that on the occasion of the Royal visit the Electricity Committee will give a supply of current free of charge to customers using it for decorative display purposes.

**Rothsay: Position of Electric Supply Undertaking.**—The Council has asked Mr. J. A. Robertson, the Borough Electrical Engineer at Greenock, to report as to the utilisation of steam from the refuse destructor for generating electricity, and also generally on the whole question of electric supply in the Borough.

**Sheffield: The Wiring Department.**—As a consequence of the recent Parliamentary decision the Corporation has sold its contracts for the supply of arc lamps to Messrs. Marsh Bros. for the sum of £125. These contracts bring in a profit of £80 per annum, after meeting all maintenance charges.

Judging from the debate at the City Council meeting last week, there is still some difference of opinion between the Corporation and the contractors in Sheffield as to whether the former are actually carrying out the spirit of the Parliamentary decision in regard to the wiring business generally. Discussions are still taking place between the two parties, and Alderman Styring, a former chairman of the Electricity Committee, hinted during the debate that a greater measure of agreement would be arrived at if the contractors were to adopt a more conciliatory attitude in the matter. The contention of the contractors is that under the Act of last year the Corporation has the right only to keep a showroom for exhibition purposes, and that a printed list of contractors should be kept or delivered occasionally to their consumers. A sub-committee, however, is dealing with the matter, and proposes to submit a recommendation to the Corporation. It is of interest to note that the expenses incurred by the Corporation in respect of the Act last year amounted to £8,749.

**Walsall: Position of Electricity Undertaking.**—With reference to the note on page 155 of our issue for March 13th, we understand that Mr. E. M. Lacey, who was recently called in by the Council, has now reported, and that the Electrical Engineer has also communicated with the Electricity Committee with regard to certain passages in the report in question. The Electricity Committee proposes to hold an early meeting to consider the whole question.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

## Generating Stations, Sub-Stations, Mains, &amp;c.

**Basingstoke.**—The Borough Surveyor has been instructed to prepare plans and estimates in connection with an electric lighting scheme.

**Bridlington.**—The Local Government Board has sanctioned loans amounting to £5,000 for electrical extensions.

**Bury St. Edmunds.**—It is proposed to erect a generating plant for the lighting of the new infirmary buildings.

**Canada.**—The Bowness Improvement Co., Calgary, requires alternators, exciters, switchboard and cable. A specification will shortly be received at 73 Basinghall Street. As the date for receiving tenders is May 31st, the above information will be of use only to firms having agents in Canada who can be instructed by cable.

**Dundee.**—Steam and feed-piping, steam feed-pumps, hot-well tank, &c. City Electrical Engineer. May 30th.

**Nelson.**—A loan of £4,000 is to be taken up for expenditure on mains and services during the next three years.

**Peterborough.**—An inquiry has been held concerning a proposal to borrow £7,000 for extensions at the electricity works. During the course of the inquiry the inspector stated that, after a visit to the works, he had come to the conclusion that it would pay the Corporation to scrap the steam engines there and buy new ones, as half the coal bill could be saved with a modern plant.

**Troon.**—Information is being sought as to the cost of an electric supply installation.

**Yarmouth.**—An inquiry has been held concerning a loan of £3,840 for the electricity undertaking. The new works include a 600-kw. alternator, switchboard, travelling crane, &c.

## Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

**Aberdeen.**—Additions to Robert Gordon's Technical College. Architect, J. O. Allan.

**Altrincham.**—New school.

**Burton-on-Trent.**—Museum and electricity showrooms.

**Croydon.**—Fire station and library in Brigstock Road.

**Dumfries.**—Sanatorium.

**Dundee.**—Extension of the Morgan Academy. J. G. Langlands, 31 Murraygate.

FOR  
STEAM JOINTS  
USE

JOHN HUDSON & CO.'S SUCCESSORS, Mansell St., London, E.

**Neath.**—New school for Glamorgan County Council.  
**Newcastle-on-Tyne.**—New elementary school, Rye Hill. Architect, J. H. Morton, Education Offices, Northumberland Road.

**Portsmouth.**—Electric lighting of workhouse infirmary. Consulting Engineer, R. J. Wallis-Jones, 50 Queen Anne's Gate, Westminster.

**Salford.**—Secondary school in Pendleton. H. Lord, 42 Deansgate, Manchester.

**Shipley.**—Additions at Otley Road school. S. Bradley, Bank Street, Bradford.

**Swansea.**—Three hundred workmen's dwellings.

#### Miscellaneous

**Birmingham.**—The Tramways Committee proposes to purchase seventy-five new tramcars at an estimated cost of £83,000.

**Liverpool.**—Twelve months' supply of stores for the Liverpool Overhead Railway Co. General Manager. June 3rd.

### TENDERS RECEIVED AND ACCEPTED

**Admiralty.**—The Admiralty has placed a contract with the Dussek Bitumen Co. for "Trinitite" Insulating Box Compound, for use in H.M. battleships, dockyards, &c. In order to secure this contract the material had to pass very severe tests, and to comply with a stringent specification, owing to the unusual extremes between heat and cold experienced under naval conditions.

**Ashton-under-Lyne.**—The tender of the Bastian Meter Co. has been accepted for the supply of 10-ampere meters.

Messrs. Chamberlain and Hookham have received a contract for two-rate meters from the Corporation.

**Bedford.**—The following tenders have been accepted:—B.T.-H. Co. for 125 meters; British Westinghouse Co. for 25 meters; Dick, Kerr and Co., for a twelve months' supply of lamps; Siemens Bros. and Co. for a twelve months' supply of cable.

**Belfast.**—The tender of Callender's Cable and Construction Co. for cable has been accepted.

**King's Lynn.**—The following tenders have been accepted:—Browett Lindley and Co. for a 400-kw. high-speed steam engine, £1,289, steam exhaust and feed-pipes, &c., £427; Roes Roturbo Manufacturing Co., rotary jet condensing plant, £305; Phoenix Dynamo Manufacturing Co. for a 400-kw. dynamo, £500.

**Kobe.**—The completion of the delivery of an order for forty-two Warner trucks by the "M and G" Truck and Engineering Co., Ltd., of St. John's House, Minorities, E., for the Kobe tramways, makes forty-two systems upon which the Warner axle has been fitted to date, including ten lines in the United States. The first British passenger coach fitted by the same firm for the Warner International and Overseas Engineering Co., Ltd., has just been completed and successfully run.

**Lowestoft.**—The Corporation has placed a contract with Messrs. Chamberlain & Hookham for car meters.

**Sheffield.**—The following tenders have been accepted in connection with the extensions of the Neepsend power station:—Turbo-alternator (Dick, Kerr) and condensing plant, Willans and Robinson, £23,119; three water-tube boilers, mechanical stokers, superheaters, economisers, pipework, &c., Stirling Boiler Co., £26,208.

**Sunderland.**—The following tenders have been accepted:—Ferranti, Ltd., 50 meters; Cable Accessories Co., 100 sets of street-lighting fittings; and Babcock and Wilcox, steel bends.

**Worthing.**—A contract for extensions to the storage battery at the electricity works has been placed with the Hart Accumulator Co.

### APPOINTMENTS AND PERSONAL NOTES

The Glasgow Electricity Committee recommends that the salary of Mr. W. W. Lackie, Chief Electrical Engineer, be increased from £1,000 to £1,100 per annum; Mr. A. Page, Chief Assistant Electrical Engineer, from £600 to £650 per annum; and Mr. R. B. MacCall, Accountant and Chief Clerk, from £375 to £400 per annum.

There was considerable opposition at the Glasgow Corporation meeting on Thursday to the proposed increases of salaries

of tramway officials, referred to on p. 268 of our issue for May 8th. Eventually all the salaries were increased, with the exception of that of Mr. James Dalrymple, the General Manager.

Professor Gisbert Kapp has been appointed Chairman of the Engineering Section of the British Association, in place of Mr. J. A. Aspinall, who was originally appointed, but has had to resign owing to ill-health.

Mr. P. W. Beatty has resigned the Managership of the River Plate Electricity Co. to take up the post of Chief Engineer to the Lacroze Tramway Co., Buenos Aires.

An Assistant Station Superintendent is required at the MacDonald Road power station of the Edinburgh Corporation. Salary £200 to £250 per annum. Applications by May 30th to Chief Engineer.

Mr. Colbeck, Assistant Mains Engineer at Dover, has resigned, and a successor is to be appointed at a commencing salary of £100 per annum.

Commercial manager required by firm of accumulator manufacturers. (See an advertisement on another page.)

First-class man required for accumulator manufacture. (See an advertisement on another page.)

Experienced battery-makers are required at Bradford. (See an advertisement on another page.)

### MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. G. Smith and Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £72 10s. to £73. (Last week £73 to £73 10s.)

**Advertising Agency.**—Mr. E. A. Hill has resigned his position as advertising manager to the Foster Engineering Co., and is starting as advertisement writer and agent on his own account at 26 Stanton Road, Wimbledon.

**Engineering and Arc Lamps, Ltd.**—This firm has now completed the repairs to its Sphere Works, St. Albans, after the damage done by the fire on March 8th. The total damage due to the fire was upwards of £3,600. The works are now in full running order, and in addition to the manufacture of their well-known arc lamps and accessories, the Company undertakes the production of any repetition work, stampings, spinings, &c.

**Change of Address.**—S. Bill and Co., Ltd., Electrical Accessories Manufacturers, have moved to larger premises at 146 Queen's Road, Aston, Birmingham.

**Electric Cooking Demonstrations.**—Gillespie and Beales (Amberley House, Norfolk Street, Strand), sole selling agents for the "Tricity" cookers, are prepared, on behalf of the British Electric Transformer Co., Ltd., to arrange with electricity supply undertakings for cooking demonstrations, by Mr. F. S. Grogan.

**Liquidations.**—A meeting of Electrocars, Ltd., will be held on Monday, June 16th, at noon, at 3 Great St. Helens, E.C., to hear the liquidator's account of the winding-up.

### COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

**British Thomson-Houston Co.**—The balance sheet for 1912 shows a profit of £30,999, and after allowing £20,000 for depreciation of plant and various other items for depreciation, there is a balance of £1,208, and this, added to the previous year's balance, leaves £8,590 to be carried forward. The report calls attention to the fact that the output of the Rugby lamp factory has been largely increased, and on account of the rapid expansion of work in other departments, the Willesden factory, which had been specially erected for the manufacture of Mazda lamps, is now being devoted to switchboard work. The Curtis steam turbine business continues to show satisfactory results, as also does the business in Mazda drawn wire lamps.

**Cape Town and District Gas Co.**—At the annual meeting which was held in London last week, the Chairman had to deal with complaints at the continued absence of dividends, which, so far as the past year is concerned, he attributed to the keen competition of the Cape Town Corporation in the supply of electricity. During the past year the Corporation has reduced its charges from 1s. to 7d. per unit, whilst there is a scale going down to 3d. per unit for large power users.

Cheques to be made payable to THE KILOWATT PUBLISHING CO., LTD., and to be crossed LONDON COUNTY AND WESTMINSTER BANK (Temple Bar Branch).

## SUMMARY

OWING to pressure on our space we have been obliged to omit our usual fortnightly cartoon this week.

THE full programme of the I.M.E.A. London Convention, from June 17th to 21st, is given on page 298.

THE results of an extensive series of tests of metal filament lamps which have been made at the National Physical Laboratory, have been published in a report by the Engineering Standards Committee. Some considerable degree of departure from their nominal rating was found in most makes of lamp. With regard to life the proportion which failed before 1,000 hours is discussed, as well as the reduction in candle-power of those surviving, with a view to framing a satisfactory standard specification. (Page 298.)

AN important feature of the joint meeting of the Institution of Electrical Engineers and the Société Internationale des Electriciens, held in Paris last week, a long report of which occupies a large part of our present issue, was a discussion on electric railway traction, based on six Papers. In one of these M. Parodi reviewed some of the economic aspects of electric traction, illustrating the subject with examples from American practice, and giving incidentally interesting comparisons of steam and electric locomotives. His views inclined to favour continuous current traction, an attitude also adopted by M. Mazen in his description of the new electrification scheme of the Ouest-Etat Railway. M. Gratzmuller took up the controversy of the systems more in detail in his Paper on

high tension continuous current traction, which he supplemented in the discussion with an almost equally warm advocacy of single-phase working. Single phase was also championed by M. Latour, who contrasted different types of motors, and was further illustrated by M. Jullian in his description of the experiments on the Midi railway. In the discussion, the coming British examples of continuous current traction at about 3,000 volts were mentioned by Mr. Roger Smith, and the important question of interference with telephone circuits was raised by Mr. Slingo and others. Another branch of electric traction was dealt with by M. Damoiseau in a Paper on petrol electric cars for railways. The Papers and discussions, taken as a whole, set forth admirably the features and relative advantages and disadvantages of the various systems of electric railway traction, and form an excellent review of the whole subject, especially as the main general points for and against the various systems are conveniently summed up in the discussion. (Pages 299-303.)

WE publish some notes on the two large power houses visited, and an illustration of the 11,000 Brown Boveri turbo-alternator at the St. Denis Station. (Pages 303-4.)

ON the consideration of Mr. Highfield's Paper on the H. T., D. C. series power transmission system, M. Thury himself took a prominent part in the discussion. (Pages 304-5.)

OUR report also deals with the visits made to the tramway and railway depôts in Paris, and the wireless telegraph installation on the Eiffel Tower, with particular reference to the arrangements for sending out international time signals, to which a lecture by Commandant Ferrié was devoted; an account is given of a lecture by M. Claude on the application of tubes of neon gas for lighting; and finally an abstract is given of a Paper by Mr. W. Slingo, describing new traffic-distributing plant which is being installed in London telephone exchanges to level the load curve of the operators. (Page 306.)

METHODS of obtaining single-phase currents from three-phase circuits are discussed in our Questions and Answers Columns. (Page 307.)

A METHOD of obscuring lamp bulbs, and a watertight gland for cables passing through bulkheads, are described on page 308.

A REVISED set of model regulations for the installation of overhead power lines has been issued by the Board of Trade. (Page 306.)

THE Loetschberg tunnel electric railway is to be opened for traffic in June. This marks an important step in electric traction, as it is the first application of the 15-cycle 15,000-volt single-phase system for heavy work.—The House of Commons has passed a motion by

which trolley-buses in London will be subject to the veto of the Borough Councils. (Page 309.)

THE criminal libel action by the Managing Director of Marconi's Wireless Telegraph Co. against Mr. Cecil Chesterton, editor of the *New Witness*, is being heard at the Old Bailey.—Action is being taken against the directors of Marconi's Wireless Telegraph Co. on behalf of some English shareholders to recover a large sum said to be the difference between the par value and selling price of 500,000 shares in the American Marconi Co.—The United States Government has placed an order with the Poulsen Co. for a long-distance wireless station at Colon.—The Marconi Co. are instituting patent infringement proceedings against the American Poulsen Co. (Page 309.)

NOTICE is given that the National Telewriter Co. intend to seek an extension of life of one of their patents, covering some details and the arrangement of telewriter apparatus. The Western Electric Co. are seeking to amend a specification for telephone switch hooks. The specifications published by the Patent Office last Thursday include one for a lead-antimony cable sheathing by the Western Electric Co., and one by the Submersible and J. L. Motors, Ltd., for a submersible induction motor. (Page 310.)

THE Toronto Electric Lighting Co. has offered its undertaking to the Toronto Government for £5,000,000.—The Galashiels Council has decided not to undertake a municipal electricity scheme.—The Suffolk Electricity Co. has made arrangements for wiring tents on the beach at Felixstowe.—Investigations are being carried out at Portsmouth with a view to evolving an attractive power tariff. (Page 311.)

AN expenditure of £52,350 is contemplated on new plant at Leicester; £24,440 at York; £3,750 at Bootle; £25,000 at Norwich; £8,000 at Hammersmith; £6,400 at Darwen; and £6,100 at Limerick.—E.H.T. switch-board is required at Oldham; 1,500-kw. turbo-alternator and condenser at Rawtenstall; an electric tramway system is to be erected at St. Michael's (Azores), and 1,157 street gas lamps are to be converted to electricity at Bristol; quantities of telephone material are required in Servia; transformers at Hammersmith; and four electric gantry cranes at Belfast. (Page 311.)

## ARRANGEMENTS FOR THE WEEK

FRIDAY, MAY 30TH.

*Institution of Electrical Engineers.*

8 p.m. Annual general meeting.

8.30 p.m. "Practical Application of Telephone Transmission Calculations," by A. J. Aldridge.

THURSDAY, JUNE 5TH.

*Institution of Mining Engineers.*

11 a.m. At Burlington House, Piccadilly. Among the papers to be read will be "Insulated and Bare Copper and Aluminium Cables for the Transmission of Electrical Energy, with Special Reference to Mining Work," by B. Welbourn.

## The London Electrical Engineers.

(TO-DAY) THURSDAY, MAY 29TH.—C. Company. FRIDAY, MAY 30TH.—D. Company. MONDAY, JUNE 2ND.—A. Company. TUESDAY, JUNE 3RD.—B. Company. THURSDAY, JUNE 5TH.—C. Company. FRIDAY, JUNE 6TH.—D. Company. Infantry Drill, 7 to 9 p.m. Technical Instruction for all Members on the Sixth Rate and for all Candidates for Higher Rating, 7 to 9 p.m. Musketry Instruction, 9 to 10 p.m.

SATURDAY, JUNE 7TH.—Headquarters open from 10 a.m. till noon.

## THE I.M.E.A. LONDON CONVENTION

THE full programme of the London Convention of the Incorporated Municipal Electrical Association, which will be held from Tuesday, June 17th, to Saturday, June 21st, has now been issued. The headquarters of the Council will be at the Hotel Cecil, and the meetings will be held, with one exception, at the Institution of Electrical Engineers, where an exhibition of cooking, heating, and other electrical appliances will be held during the Convention.

The Convention will be opened by Mr. W. Duddell, President of the Institution of Electrical Engineers, on the Tuesday morning, and the address of Mr. C. E. C. Shawfield (ex-

president of the Association), and a Paper by Dr. S. Z. de Ferranti on "Prime Movers for Electric Power," will be read. In the afternoon visits will be made to the generating station of the London Electric Supply Corporation at Deptford and the Corporation Electricity Works at West Ham.

At Wednesday morning's meeting discussion will be held in camera by members and delegates only on the I.M.E.A. Bill and Heating and Cooking. The London Electric Railway Power Station at Lots Road will be visited in the afternoon, and the Annual Dinner will be held at the Hotel Cecil in the evening.

The Thursday will be spent at Kingston-on-Thames. In the morning, after an address of welcome by the Mayor at the Empire Theatre, Papers will be read by Mr. J. Christie on air filtration, and by Messrs. W. H. L. Watson and R. J. Mitchell on electric vehicles. The latter Paper will be introduced by Mr. A. H. Seabrook, and a demonstration of battery-driven vehicles will be given after the meeting. A river trip, including Weybridge and Hampton Court, has been arranged for the afternoon.

On Friday the Annual General Meeting will be held, and a Special General Meeting to consider alterations in the Articles of Association, and on Saturday morning a visit will be paid to the Humphrey gas pump installation at the new Chingford reservoir.

## RATING AND LIFE TESTS OF TUNGSTEN LAMPS

A REPORT on a long series of experiments on tungsten filament lamps, which have been carried out by the National Physical Laboratory, has been published by the Engineering Standards Committee in two parts, one containing the text and the other curves by which it is accompanied. The tests in question were undertaken at the request of the Sectional Committee on Electrical Plant in order that the sub-committee, which is considering the drafting of a general specification for glow lamps, might have as much detailed information as possible. The experiments were directed mainly upon obtaining data as to the degree of uniformity in batches of lamps of given rating and their behaviour on life tests.

A very large number of lamps were tested, but the names of the makers are not given. The tests of initial rating are plotted in "target diagram" form, and the general conclusion is that individual lamps at present on the market vary considerably from their nominal ratings. The case of one maker, where the lamps were taken from a consignment supplied to a Government Department, is, however, cited as showing what can be done by careful rating. Forty per cent. of the batches tested came within the limits required by the British Standard Specification for carbon filament lamps ( $\pm 12\frac{1}{2}$  per cent. for c.p. and  $\pm 8$  per cent. for watts), and the same percentage fell within certain limits based on watts per candle-power, which have been put forward by some of the British lamp-makers in a suggested draft specification framed on the lines of the official specification employed in the U.S.A. On the basis of watts alone, 48 per cent. fulfilled the Standard Specification and 79 per cent. the makers' requirements.

In the life tests the lamps were all run initially at 1.2 watts per c.p. As this condition was found, by previous experience, to give a diminution of c.p. of about 20 per cent. after 1,000 hours (a basis suggested by the American definition of "life" as the number of hours, until the c.p. decreases to this extent or until the lamp breaks if within that period). In the tests 71½ per cent. of the 220-volt lamps and 32 per cent. of the 105-volt lamps broke before 1,000 hours, and these had average lives of 441 and 540 hours, and those which survived diminished, on the average, 19.1 per cent. and 19.6 per cent. respectively for the high and low voltages. The general bearing of the results of the tests is discussed at some length. It is remarked that the test life of a lamp is terminated either by the burn-out of a filament or by the c.p. falling a certain amount after a specified period. The fall of candle-power is very sensitive to the watts per candle, the burn-out only so to a small extent. Finally, the following way of treating the matter is recommended as preferable to the American specification: namely, to "specify that when the lamps are run at a certain prescribed efficiency, the average fall in candle-power of those lamps which reach 1,000 hours shall not exceed 20 per cent. of the initial candle-power," and "that the average number of burning hours, of all the test lamps of a given rating, up to 1,000 hours, must not be less than a given amount." In this figure, for example, 850 hours is suggested for 100-volt 50-watt lamps, 750 hours for high-voltage 50-watt lamps.

## JOINT MEETING OF THE BRITISH AND FRENCH INSTITUTIONS OF ELECTRICAL ENGINEERS IN PARIS

THE Joint Meeting of the Institution of Electrical Engineers and the Société Internationale des Electriciens was held in Paris last week at the invitation of the latter Society. As was stated in our last issue, over 100 members accompanied by several ladies crossed to Paris on the Tuesday, and others joined the party there. The Members of Council who took part in the meeting were Mr. Duddell (President), Prof. G. Carey Foster (Past President), and Messrs Judd, Snell, Hammond, Highfield, Jenkin, and Roger T. Smith.

The President of the French Society, in opening the meeting on Wednesday, welcomed the visitors and thanked them for coming in such numbers. He added that the Société Internationale des Electriciens had not forgotten the cordial reception given to their members in England in 1906.

### Electric Railway Traction.

Six Papers on electric railway traction by French authors were then formally read in abstract at a very rapid rate in French by M. Joly, the General Secretary of the French Society. We give the main points in the several Papers below. Translations of the Papers, more or less in full, may be obtained from Mr. Rowell, Secretary of the Institution of Electrical Engineers. A short discussion on the Papers took place on Wednesday, and the discussion was resumed on Friday.

#### HIGH-TENSION CONTINUOUS CURRENT.

M. L. GRATZMULLER dealt in the first Paper with the high-tension direct-current system. When the power station is at a considerable distance from the track, three-phase generation, he said, was the obvious solution, but to keep down the weight of the turbo-alternators a frequency greater than 25 was desirable unless rotary converters were to be used in the substations. The motor generator for pressures below 1,200 volts was too expensive. The cascade converter did not show to advantage unless the frequency was high, e.g., 50 cycles per sec., or unless the output was sufficient for the A.C. stator to be supplied with high-tension current. For rotary converters, 50-cycle current could be satisfactorily used, but the continuous-current pressure could not be raised to more than 750 volts. For higher pressures the converters should be put in series.

If the station was so near the track that there was no need for a higher transmission pressure than 1,200 or 2,400 volts, dynamos driven by water turbines would work satisfactorily up to 1,500 volts with a single commutator, and machines with two windings and two commutators could give the higher pressure. With steam turbines he preferred to generate alternating current and to transform it. In this connection, the Author said that more and more interest was likely to be taken in increasing the speed, and consequently the frequency, of turbo-alternators. The mercury converter, whatever might be the frequency, allowed the alternating current to be rectified with a constant fall of pressure. It was being perfected; apparatus of a capacity up to 500 kw. already existed, and for high pressures its efficiency was nearly unity. With regard to overhead conductors, 3,000 volts' pressure would probably be the safe limit for some time to come, but since a current of 500 amperes at this pressure supplied a power of 1,500 kw., it would appear that powerful locomotives could only be utilised where a third rail was installed. Dealing with the motors, the Author inferred that with the same internal diameter, length of iron, and weight of windings it should be possible to obtain the same torque in normal working, whether the motor was wound as a continuous current or three-phase induction motor. Although the single-phase motor was clearly heavier, the difference was not so great as was formerly given, the difference being only 15 per cent., and not  $\frac{1}{\sqrt{2}}$ .

The Author then passed on to a comparison of the shunt and series motor, and the commutation of series continuous and alternating current machines, the result arrived at being that continuous-current motors with distributed compensating windings would probably come to be adopted. There was no special technical difficulty in the design, and it seemed that the pressure of 1,200 volts per motor should be easily reached when multiple units were employed, and 1,500 volts for locomotives. Unfortunately, at low powers it would often require two turns per coil; series winding would naturally be used. A locomotive of 2,000 h.p. at 3,000 volts could thus be constructed with two motors in series or motors having two commutators. The current required would then be approximately 500 amperes. The use of aluminium for the rotors appeared very suitable, and the increase in electrical resistance could be largely compensated for by the increase in peripheral speed for the same centrifugal force. Owing, also, to the recent improvement in gear cutting,

reduction gear could be used, as was done for the locomotives for the Lotschberg. This increase in peripheral speed, coupled with forced ventilation, would enable the weight of the motors to be reduced by about 50 per cent. Comparing enclosed, semi-enclosed, and locomotive motors, the conclusion was that auxiliary fans or water-cooling was not justified; each rotor should act as its own fan, and produce a current of air which would enter near the shaft through a bearing, and pass through the centre of the commutator and the iron stampings of the rotor. Numbers of small passages should be avoided, and the commutator might be provided with vanes.

For the controlling arrangements, any of the well-known systems could be employed; but with the usual American practice of providing two motors, each for half the total pressure, and connecting them in series, it was to be feared that slipping might cause an undue pressure to come on one motor. On the question of braking and regeneration, especially where starting and stopping are frequent, there was the solution in the use of boosters on one or more cars. If  $V$  were the pressure of the line, and the booster pressure varied from  $-V$  to  $+V$ , and if one of the terminals were earthed, no point of the motors could be at a pressure greater than  $\pm V$ . During the periods of regeneration, the only essential point would be that the excitation of the motors should not be provided by putting them in series with the field magnets. It might evidently be obtained, more or less directly, from the boosters, or from an auxiliary exciter attached to the machine. Moreover, for the starting period it was desirable that the motors should retain their series characteristics. If merely varying the excitation of the booster would allow the whole control apparatus to be done away with, and the extra power taken by the dynamo was only equal to the total power of the driving motors, it followed that great peripheral speeds and artificial cooling made this solution the one to be adopted. In this connection, the system due to Messrs. Macfarlane and Burge, using the C.M.B. converter (ELECTRICAL ENGINEERING, Vol. V., p. 629, and Vol. VIII., p. 101), was mentioned, and criticised thus: For equal speeds there was no saving of material in the armature, but the length could be reduced whilst the diameter was increased. On the other hand, there was no longer any symmetry in the machine. The magnetic bridges between the poles had to carry all the flux from one pole, and not half, as in a multipolar machine; moreover, the leakage from pole to pole would be very large, the armature reaction would be unsymmetrical in regard to the short-circuited brushes, and it was difficult to see how to utilise auxiliary poles or a compensating winding in this machine.

In conclusion, the equipment of the principal manufacturers was briefly described, and a list of undertakings working at from 600 to 3,000 volts continuous-current line pressure, including those systems in America using both 600 and 1,200 volts, was given. Finally, it was pointed out that the name high-tension continuous-current traction is not very happy, as it implies an entirely new type of apparatus. As a matter of fact, it only marked steady development. The trains from Villefranche to Bourg-Madame worked at 850 volts. Sections of the Buda-Pesth system were run at 1,000 volts; and locomotives taking current at 2,400 volts were in operation, while 3,000 volts was talked of. This progress was justified by the improvement in commutation and to recent methods of insulation by means of mica and impregnation. The advantages of continuous current were principally the large starting torque, good commutation, and light coaches. The drawbacks were the use of an exposed high-tension rotating part—particularly dangerous in damp localities—the use of a commutator, and the control of the large currents necessary when a large amount of power was required.

#### SINGLE-PHASE.

M. MARIUS LATOUR contributed the second Paper, which was chiefly devoted to a consideration of series and repulsion motors. Referring, first, briefly to mechanical considerations, however, he recommended that the motors should be mounted on springs, so that dangerous resonance effects, such as arise at certain speeds with mechanical transmission, can be avoided, in so far as these arise from fluctuations in the torque. In addition to the mean rotation of the motor, there is an oscillatory movement which is liable to produce a leading wattless E.M.F. in the armature. He then referred to extensive tests which had been carried out by the Compagnie du Midi with the following motors:—(1) the simple repulsion motor (Brown, Boveri) and the compensated repulsion motor (A.E.G.); (2) the series motor with a transverse local field for compensating the electromotive force of short-circuit under the brushes (Jeumont), and the series motor with an elliptical field (French Thomson-Houston Co.), and the well-known Westinghouse series type. The Author remarked that in the repulsion motor at speeds above synchronism the transverse field increases in strength, the iron

# BROWN-BOVERI TURBO-GENERATORS.

*In this issue of "Electrical Engineering" (page 303) a short account is given of the typical BROWN-BOVERI plant at the ST. DENIS POWER STATION, PARIS, in which are installed NINE turbo-generators of 6,000 Kilowatts and one of 11,000 Kilowatts, generating energy directly at 10,500 and 12,300 Volts.*

losses increase, and commutation becomes unsatisfactory, until, at  $\sqrt{2}$  synchronous speed, commutation is worse than that of the series motor. The compensated repulsion motor, on the other hand, works at approximately unity power factor, due to the property of commutator motors with short-circuited brushes of having no inductance at synchronous speed and negative inductance above that speed, even when supplied with simple alternating current. As indicated by the name, the other two types have an additional winding perpendicular to the brush axis connected up so as to give commutating fields. The results of mathematical investigation of these motors are that in all cases the commutator should run at a high peripheral speed, for which gearing is necessary; this is used on the Jeumont and Westinghouse locomotives, and on the Oerlikon locomotive for the Lötschberg, and appears to give entire satisfaction. At a frequency of 15 the repulsion-type motors are heavy, and the efficiency does not improve with lower frequency, whereas with series motors it approaches more nearly to that of a continuous-current machine. With regard to commutation, the narrower the auxiliary poles the smaller the losses. This necessitates a small rotor tooth-pitch. Thus a large number of poles, high speeds, and small air-gaps are required. At a frequency of 15 commutation losses could be reduced to 0.25 per cent.

## ELECTRIFICATION OF THE CHEMIN DE FER DU MIDI.

M. JULLIAN gave some interesting information in this Paper. Some of the track is standard gauge and some metre gauge. When all the proposed electrifications are completed there will be 622 km. of line electrified, of which 327 km. are now working, and 227 are to be electrified under an agreement with the State dated July 4th, 1908, and 68 km. of line crossing the Pyrenees. If the generating stations at Eget and Toulon can supply sufficient energy, it is also proposed to electrify the line from Perpignan to Villefranche, in the eastern Pyrenees. The lines to be constructed in the Pyrenees have steep gradients, chiefly between 1.5 and 3.2 mm. per metre, and the mean practicable speed is about 60 km. per hour. Current at 12,000 volts, 16 cycles, is used throughout. It is generated at 6,000 volts single phase, transmitted at 60,000 volts to five sub-stations, where it is stepped down to 12,000 volts and fed into the overhead conductor. Balancing the extra cost of the generators for single-phase supply over three-phase against the reduced cost for switchgear and transmission lines, the advantage is on the side of the former. In the experimental line from Villefranche to Vernet-les-Bains, six types of overhead equip-

ment have been established: four of these belong to the simple catenary type, one to the double catenary, and one to the rigid type. The spans are 100 metres, 60 metres, or 50 metres, and the longer sections are provided with compensating arrangements. As a result, it was found that on the lines comprising fairly numerous curves of a radius between 350 and 800 metres, and worked over by trains at speeds of between about 75 to 80 km. per hour, but not exceeding 90 km. per hour, the choice should fall upon the simple uncompensated catenary type for spans of between 50 to 60 metres, and with pull-offs on the curves to bring back the overhead conductor towards the centre of the track when necessary. The catenary cable should in this case invariably be anchored to the insulator at each bracket. With regard to poles, those made of reinforced concrete are too expensive and too heavy for existing lines, and the "Midi" type of pole, composed of old rails fastened together, is very suitable for single-track lines. For double track, however, lattice poles must be used. The high-tension transmission lines to be used, generally two in parallel, are of aluminium, and most of the insulators are of glass; some, however, are of porcelain. On the question of cost, on the lines already constructed it comes out to about 19,500 fr. per kilometre for single track, using "Midi" poles, and 21,500 fr. per kilometre for double track.

Tests are still in progress with locomotives and motor-cars. The conditions are that the locomotives must be capable of starting a 400-ton train on an up-grade of 11 mm. per metre, and in addition of hauling a train of 100 tons at a speed of 60 km. per hour, and a train of 280 tons at a speed of 45 km. per hour over the hilly section from Ille to Villefranche, which has long and numerous gradients of 17 mm. per metre, and some even of 21 mm. On a down-gradient these locomotives are to be able to deal, by electric braking alone, with the same loads at speeds capable of being regulated by the driver between the up-grade speeds and one-half of those speeds. The electric braking may be regenerative or else by resistances. The motor-cars must haul a train of 100 tons, motor-car included, over the same gradients at a speed of 65 km. per hour. Three locomotives have satisfied the conditions. They were constructed by the Ateliers de Constructions Electriques du Nord et de l'Est, by the French Thomson-Houston, and Westinghouse Companies. The motor-car constructed by the latter firm also satisfied the conditions. For the protection of telegraph lines from disturbances, apparatus due to M. Girousse has been found successful and adopted, and with regard to the telephone, the Administration is about to replace ordinary insulators by others

of greater insulation resistance, to transpose the two lines every 300 or 400 metres, and to insert transformers between the lines and the receiving apparatus, to save users from risk of shocks.

#### THE PARIS SUBURBAN SYSTEM OF THE (WESTERN) STATE RAILWAYS.

M. A. N. MAZEN commenced his Paper on this subject by some data giving an idea of the magnitude of the Ouest-Etat railway system, which involves some 1,640 trains per day entering and leaving Paris. Due to the mixture of suburban and long-distance traffic and the rapid increase of both, a condition of congestion has been brought about which necessitates increase in the carrying capacity of the lines such as cannot be effected as long as steam traction is used exclusively. The Author says that it is useless to try to exceed a maximum of 12,000 passengers per hour per double track with steam, whereas the well-known advantages of electric traction enable this to be far exceeded. The Métropolitain, with trains of five coaches carrying 500 passengers, is able to deal with an hourly total of 12,000 passengers. With carriages 3 m. instead of 2.40 m. wide, and 22 m. instead of 14 m. long, and assuming eight carriages per train, the enormous figure of 40,000 passengers per hour is reached, or, considering seats only (no standing), that of 20,000 passengers per hour. No section of a steam line, he says, can deal with more than 100 trains in each direction per day, whilst it is agreed that on electrified lines this figure may reach 350. Such developments would also hasten the increase of traffic, and in this connection it is remarked that the electrified line from the Invalides to Versailles has shown traffic increases of from 12 to 13 per cent. per year, while the other steam lines showed increases of barely 2 or 3 per cent. The Author then briefly reviewed the reasons for adopting continuous-current, 650-volt, third-rail system in preference to single-phase or a higher continuous pressure, including the lighter weight of the equipment and the avoidance of trouble with overhead lines and of interference with telephone circuits, &c. The system is also used for all the existing heavy electric traction schemes in Paris. In the scheme, current is furnished by sub-stations receiving energy in the form of alternating three-phase current at 25 cycles, 15,000 volts, by duplicate feeders from two generating stations. To avoid trouble from frost after a thaw, a conductor rail with under collection was proposed. This rail weighs 76 kg. per metre. It is carried by supports of impregnated wood of a type similar to that used on the Invalides-Versailles line. A single type of electric carriage is used, built to contain all the elements required for suburban service, namely, guard's van and first and second class compartments. This coach can carry 100, including "straphangers." During much of the time the service will be carried on by single-coach trains. During the time of heavier traffic, and on the more busy sections, the trains will be composed of several similar coaches. It is also intended to run special electric trains for parcels service. The motor-coaches collect the current by a special universal shoe, either from the upper or under surface of the rail. The sub-stations, placed wherever possible at junctions, contain rotary converters of 1,500, 1,000, and 750 kw. output. Their distance apart varies from 3 to 8 km. A control system allows a variation in the voltage of the supply, and of several sub-stations being put out of action during slack hours. The construction and working of the two power stations at Mouligneux and at Bezons has just been entrusted, after public tender, to an industrial syndicate. They contain turbine units of 5,000 kw., and when the installations are complete will have a capacity of about 60,000 kw., and will furnish about a hundred million kw.-hours per annum. There is a sliding scale of charges under which, when the stations are finished, energy will be sold to the State at an inclusive charge of about 5 centimes per kilowatt-hour. This scale contemplates the ultimate utilisation by the State of the energy coming either from the Rhône or from the coal-mines in the north.

#### PRACTICE IN THE UNITED STATES.

M. H. PARODI in a long Paper sketched, first, the differences between American and Continental conditions, emphasising particularly the greater rate of increase of traffic in the United States, and the reasons why, with the longer distances, larger trucks and heavier trains, merchandise could be carried in America at about half the cost at which it can be in Europe. The question of suburban traffic was also taken up, and the facilities for increasing the frequency of trains afforded by electric traction was particularly dwelt upon. From statistics it appeared that in America the logarithm of the receipts was about proportional to twice the logarithm of the increasing population. Statistics were also given with regard to electric tramways in America, and comparisons were made between single-phase and continuous-current systems, from which it appeared that the cost per car km. on the tramways, which is 0.5 franc for D.C., should come to 0.59-0.60 francs for single-phase, as a result of the greater cost of repairs and maintenance. The differences between these systems of traction as applied to railways would be much greater. The relation between traffic and expenses which must exist for electrification to be remunerative was next investigated. Assuming the net

cost per car km. to be 0.6 franc, and the average cost of transport per passenger km. 0.06 franc, then, if the total annual number of car km. per km. of line be  $N$ , and the average number of passengers per car  $f$ , the relation between the traffic and the annual revenue will be for a ratio of working expenses to receipts of 60 per cent.  $0.60N + 10,000 = 0.06Nf / 100$ .

On this basis, the Author calculates that the passenger traffic of the New York, New Haven, and Hartford Railway, which is quite exceptional, would almost justify a general electrification of the lines of that company, but for the New York Central Railway and the Pennsylvania Railway the electrification should be restricted to those lines where the average traffic per car is sufficient. Comparison follows between the continuous-current working of the New York Central and the single-phase working of the New Haven lines. The former affords a suburban service by means of motor-cars, whilst the latter employ almost exclusively locomotive traction. The four 600-h.p. single-phase motor-cars in service only ensure a few trains a day. There is reason to believe, continues the Author, that the use of single-phase motor-cars has not been extended owing to their weight and high price. Even by admitting that the cost of traction is exactly the same for the two systems, single-phase working will be more expensive than continuous-current working by reason of this extra weight, and the service will certainly be inferior owing to the insufficiency of power of the motor-cars. Figures are then quoted to show the much higher cost of maintenance of the single-phase equipment.

Some questions involved in real main-line service were next gone into. The author thinks that in the future, with continuous current, it is probable that the pressure will be limited to 1,200 volts, at least for the electrification considered by the

New York Central Railway, so as to be able to retain without change the inverted third-rail conductor. As regards ordinary alternating current, he has reason to believe that a method of supplying current will be adopted similar to the three-wire continuous-current distribution by connecting the running rails to the centre of a transformer winding at 22,000 volts, of which the terminals would each be connected to one of the two overhead conductors serving adjacent lines. Trouble with neighbouring telephone lines may be diminished by crossing the outer conductors at intervals. Whatever system of traction is adopted, the ordinary method of working railways ought to be retained, and the trains should be drawn by as powerful, light, and fast a locomotive as possible. Curves given in the Paper of the draw-bar pull of different classes of steam and electric locomotives are reproduced here. It is pointed out that these electric locomotives were really constructed to develop their maximum power at about 60 km. per hour, corresponding with a suburban service. In the United States there are no continuous-current or single-phase locomotives which are really very powerful at their maximum running speed, whereas there are very interesting examples in Europe of three-phase locomotives. The locomotives now in use in the Simplon Tunnel develop at 70 km. per hour a draw-bar pull of 6,000 kg.; the new loco-

motives which are under construction, however, will weigh 86 tons, and will develop 3,000 h.p. at this same speed of 70 km. per hour. The Italian State Railways, also using three-phase equipment, have actually ordered 10 locomotives able to develop 2,000-2,400 h.p. at 100 km. The Author suggests that, while locomotives with a series characteristic are suitable for suburban conditions, something more approaching a shunt characteristic is required for main-line working. In this respect, three-phase locomotives would be far superior to the others, as their weight would be considerably less, being something like 30 kg. per horse-power. The lightest single-phase locomotives that have been built, at least in America, weigh more than 60 kg. per horse-power. In the United States the question which is primarily occupying the manufacturers and the railway companies is what method of drive to adopt for the motor axles; the three companies which have in service locomotives capable of hauling express trains have employed radically different methods, viz., connecting rods, a direct drive, and a drive through gear and a hollow shaft. For high speeds the first seems to be preferred. The obtaining of high-speed locomotives with total adhesion and as light as possible appears to be the vital problem of main-line traction. Two types of locomotive being built are described. One, of the American General Electric Co., for the New York Central, has eight 300-h.p. direct-drive motors on each axle. It is articulated throughout, and the single body rests on two trucks, each with two bogies. The other, being built by the Pennsylvania Railroad, more nearly follows steam practice, and has four driving axles with a very high centre of gravity, and formed in two parts, each part carrying four driving wheels and a supporting bogie. The axles of the wheels are driven through connecting rods, cranks, and intermediate shafts by a 1,000-h.p. motor. The paper concludes with a few notes on mountain railways, including the Cascade Tunnel line of the American Great Northern Railway, and it is mentioned that the Southern Pacific has just entrusted the General Electric Co. with the complete installation of electric traction on a long mountain line near Denver.

#### PETROL-ELECTRIC SYSTEMS.

M. J. B. G. DAMOISEAU, after brief reference to the Heilmann locomotives as the first "mixed" vehicles, and a few general notes, proceeded to describe some typical petrol-electric cars which have been built for railways. That of the Société Anonyme de Locomotion Electrique, built in 1904-5, and the car built about the same time by the North-Eastern Railway, were both really experimental vehicles, and were examples of pure electric transmission with control both by variation of the generator field and series-parallel connection of the motors. A battery was used for excitation and for starting the engine. The first line to be run regularly by petrol-electric cars was the Hungarian Arad-Osanaad Railway, and descriptions are given of the de Dion-Bouton and Westinghouse cars there used. These are controlled partly by variation of the speed of the engine as well as by series-parallel arrangements and field regulation. A large number of the Westinghouse cars are in use in various parts of Europe. Petrol-electric cars made by the A.E.G. and the Bergmann Companies are in use on the Prussian railways. The generating set is carried on one bogie, and the motors on the other. Variable-pressure control is used, and a battery is provided for excitation and auxiliary services. Other cars with purely electrical transmission are the large cars of the American General Electric Co., with their special stream-line bodies, a small car of the B.T.H. Co. in use on the G.W.R., and the cars equipped by Allmänna Svenska Elektriska Aktiebolaget for the Swedish State railways, and driven by Diesel engines. The Pieper mixed transmission method is next described. In this system there is a mechanical connection by a magnetic clutch between the engine and the wheels, and the extra torque required for starting, &c., is supplied by a motor taking current from a battery, which is charged by the same machine acting as a dynamo at times of light load. Finally, the Author describes the Thomas petrol-electric system (see ELECTRICAL ENGINEERING, Vol. VIII., p. 627) in which the former is transmitted partly mechanically by epicyclic gears and partly electrically. This system is in use on the South African railways. The Author dwells upon the advantages of such cars with their flexibility of operation for light traffic, and after a few words as to avoidance of fire risk, compares the different systems, preferring the purely electrical methods, in that the engine is better protected from shock and can be placed irrespective of the position of the axles to be driven, the engines need not be reversible, and for other reasons. He gives the approximate total cost of running, including capital charges, at 0.0177 to 0.0249 francs per ton kilometre, using benzol as obtainable in France. As regards "service efficiency," he quotes the case of cars in Hungary, which have run 50,000 km. without being taken out of service for repair. A list mentions 124 cars in actual use, and as regards the relative merits of petrol-electric and other systems the author concludes his Paper as follows:—"The four types of independent motor vehicles are at present: steam, accumulator petrol with mechanical transmission, and petrol-electric. Accumulator cars have, however, been abandoned, and as the petrol engine with mechanical

transmission has not been found sufficiently flexible, there remain, therefore, at present only the steam motor-car and the petrol-electric vehicle. The characteristics previously enumerated for petrol-electric cars emphasise the shortcomings of the steam motor-car, and the conclusion may therefore be drawn that if the use of independent motor vehicles continues to develop—and there is no reason why it should not—then petrol-electric motor vehicles will preponderate."

#### Discussion.

M. MAZEN opened the discussion by recapitulating some of the points in his Paper, and adding some supplementary remarks. He explained that the problem of the electrification of the suburban lines of the Ouest-Etat Railway was largely governed by the fact that the rush-hour traffic was about eight times that of the dead hours, whereas the usual ratio on suburban lines might be regarded as 3:1. The ease with which the power of each train could be varied was therefore of importance, and in consequence motor coaches have been adopted and trailers not employed; a train will consist of one, two, three, or four coaches. There are no short-radius curves to be dealt with as there are on the Métropolitain, and long coaches could be used; the bodies measure 22.36×2.93 metres on the latest trains. On the Métropolitain the speed is only from 30 to 35 km. per hour; nearly double is wanted on the Ouest-Etat, and the newest trains will have four-motor coaches, and 640 h.p. per coach. At first 2-axle bogies were used, but the latest type are 3-axle, with a geared 160 h.p. motor on the front and back axle of each bogie. This works out to 9 h.p. per ton. On the question of single-phase v. D.C., M. Mazen said that single-phase with an overhead conductor was easy for single track and light traffic, but directly there was a case of a large station with several lines of rails, the gain in using single-phase A.C. was neutralised. The London, Brighton and South Coast Railway in England must have been complicated and dear. But even in the case of ordinary double track the permanent-way engineers were opposed to overhead construction, especially in the form of two trolley wires suspended from span wires, as, in the event of an accident causing a derailment, two or three posts knocked down on either side of the track would stop the whole line, and temporary single-track working during the emergency would be impossible. At Batignolles and St. Lazare on the Ouest-Etat system there were 20 to 30 lines of track respectively. Each track must be absolutely independent of the other, and this was always possible in third-rail working.

Mr. ROGER T. SMITH spoke chiefly on Mr. Parodi's paper, which, he said, was of particular value in showing why the electrification of railways was a different problem in the United States from that in Europe. The Paper, he said, was the clearest statement of the case which he had had the pleasure of reading. For suburban lines the engineering problem of electrification had been solved, and merely the commercial problem remained. Nobody need hesitate to employ the third-rail system for suburban traffic. In the case of hilly districts, he pointed out, there was a critical gradient above which electric driving would always pay, and in spite of the work which had been done in Italy, he thought that either D.C. or single-phase was better than three-phase, owing to the series characteristic torque, and for speeds up to 31 miles per hour they were better than the steam for the same reason. M. Jullian had rightly pointed out that regenerative braking did not spoil the single-phase motor in other respects. There was, he said, an immediate future for electric traction for mineral traffic in hilly districts, and they might expect to see several examples of this in England during the next few years. The North-Eastern Railway were now taking the lead in a line to Middlesbrough, using very high-tension D.C. overhead, and in addition there would be another 3,500-volt line started in England quite soon (see ELECTRICAL ENGINEERING of April 4th, 1912, p. 179). To the curve of tractive effort in M. Parodi's paper he had added another (shown dotted in our illustration); giving the result of a test with a dynamometer car on a 4-6-0 type of locomotive drawing a passenger train from London to Plymouth (226½ miles) without a stop, at an average speed of 54 m.p.h. The train weighed 405 tons, of which the locomotive accounted for 117 (viz., 28 per cent.). At 70 m.p.h. the draw-bar h.p. was 730, and no electric locomotive had yet been built which could give this at such a speed. For general purposes, however, the actual strength of the draw-bar was the limiting factor—it was limited to 12 tons, corresponding to a train weighing 2,500 to 3,000 tons. There were in Great Britain, he said, some 500,000 private freight waggons not under the supervision of, and not made by, the railway companies; they represented a capital of some sixty million pounds sterling, and their draw-gear could not be relied upon to stand more than 12 tons.

Mr. ROBERT HAMMOND, speaking in French, offered his thanks and congratulations to the Authors of the six French Papers. It was very true, as M. Jullian had said, that the question was entirely an economic one, and he considered that it was largely dependent on works costs.

M. BOCHER spoke on M. Damoiseau's paper, and referred to the large variety of uses which existed for "electric coupling."

The discussion then stood adjourned until Friday, when it was re-opened by

M. MARIUS LATOUR, who reviewed some of the points in his Paper, and also dealt generally with the subject. There had, he said, been much discussion on the question of frequency for single-phase traction, but as the contact surface on the commutator depended on the frequency, there was no doubt that the cost of maintenance of a 25-cycle system was nearly double that of a 15-cycle system. He contended that the employment of auxiliary poles in the case of single-phase motors introduced no complication at all. On the question of weight, it was, of course, admitted that the single-phase system resulted in heavier locomotives; but one must not, he said, forget the starting point from first principles, which was that single-phase was introduced to give the advantage of a single contact wire carrying current at high tension. He regretted the dividing up of single-phase systems into two sharply divided schools of practice, and advocated a combination of the best points in all the methods. He touched briefly, but without being very sanguine, on the ultimate possibility of employing a rotary converter on a locomotive, so as to enjoy the advantage of high-tension single-phase at a comparatively high frequency on the trolley and the D.C. motor for driving, and he also referred to the mercury vapour rectifier. As to the immediate practical application of the latter, he was not very optimistic either, but he cited a case in which a 1,200-volt, 1,000-ampere mercury rectifier had been in continuous use for seven days. In connection with the controversy as to frequency, he reminded the meeting that when 15 cycles was employed for 3-phase working nobody had anything against it. This low frequency also diminished telephone disturbances, and, to minimise these, one must aim at a pure sine curve and avoidance of higher harmonics.

M. GRATZMULLER agreed that the main objections to the single-phase system were the increased weight and the increase in the surfaces of commutation. He believed that the repulsion motor might now be ruled out of court, and that the field was left to the series compensated motor. The advantage of single-phase over H.T.D.C. only amounted to 15 per cent. He referred humorously to the effective development of the single-phase system being dependent upon the proper joining up of the ideas of the designers and the experience of the engineers in the shops, and said that the problem was in fact throughout one of joining up, for one of the chief difficulties was in joining the resistance connections to the commutator. There was no doubt that the use of resistances to diminish the E.M.F. between short-circuited segments of the commutator was the correct thing, for by their means the size of the commutator could be enormously reduced. The difficulties were being overcome, and by placing the resistances in supplementary slots leading out of the main slots, and not in the main slots themselves, a satisfactory arrangement was secured without increasing the size of the armature at all. Dealing next with regenerative braking, M. Gratzmuller said that the objection had been raised that this was difficult with single-phase working, but although it might not be quite so good as with 3-phase, the difference was not serious. References to patents brought M. Gratzmuller into conflict with M. Latour, and a sharp passage of arms ensued on the former saying that he had patented, and subsequently abandoned, one of the methods adopted by M. Latour. Returning in his concluding observations to the question of contact surface at the commutator, M. Gratzmuller said that the same surface as with ordinary D.C. motors would be arrived at, nay, we were reaching it—in fact, we had already reached it, for a 420-volt Westinghouse single-phase motor had a contact surface of the same order as a 500-volt D.C. motor. The advantages of A.C. over D.C., he concluded, were regenerative braking, and the possibility of varying the speed without breaking the circuit. He had, he said, proposed and patented a transformer which could be carried on the locomotive to convert single-phase into 3-phase. A very simple method was to employ a squirrel-cage rotating transformer, and to regulate by rotating the brushes, but he did not recommend this.

The fact that M. Gratzmuller had read a Paper in favour of the H.T.D.C. system, and had shown himself an advocate of single-phase in the discussion, provoked considerable amusement.

M. PARODI, who next spoke, said that he was not an opponent of single-phase working, but was sceptical about accepting figures and statements merely given verbally during visits to inspect various lines and systems. The single-phase people, moreover, were now always talking of patents and not accomplishments.

M. GIROUZZE, of the French Post Office, referred to his system for neutralising disturbances in telegraph circuits. It was, however, merely for the purpose of dealing with the fundamental wave, and did not remove the noises due to harmonics which are so disturbing to telephone lines.

Mr. SLINGO (Engineer-in-Chief of the British Post Office) said that it would be a serious thing if he woke up one morning and found that the 750 million pounds worth of telegraph and telephone lines for which he was responsible were useless owing to disturbances from electric railways. The total power used for the latter in Great Britain was still relatively small, and it must not be forgotten that the British telegraph circuits would be particularly liable to disturbance owing to the high speeds at

which they were worked. The risk to railway-signalling circuits, which are worked with earth return, was also great, and he instanced a case between Dublin and Howth in which the signalling wires had had to be doubled on this account. In London the trouble had been got over incidentally and not intentionally by the conversion of the telephone system to common battery working, which had the effect of increasing largely the resistance of the circuits and the voltage applied. Inductive effect due to D.C. traction had thus been effaced. The problem, he said, seemed to be how to divide the earth between the telegraph and traction engineer—a joke which was equally appreciated by the French and English members. In one test he had made, he had cut away the lead sheath of a cable for a few inches, and had bridged it across with an ammeter; several amperes flowed continuously, and the fluctuations in the load were clearly seen. With single-phase working, if the harmonics could be avoided, there would be no difficulty in overcoming the other effects. He had made tests on a telegraph circuit 20 ft. away from a 7,000-volt electric railway line, and running parallel to it, and actually measured a potential of 600 volts. By placing an earthed wire parallel to it and between the railway and the telegraph line, this voltage had been reduced to 50. In another case he had erected a loop of telephone line, 3 miles long and as perfectly revolved as possible, parallel to a single-phase traction circuit, and the telephone connected to it had "absolutely screamed." If this occurred when every precaution had been taken, it seemed impossible to avoid serious effects on ordinary circuits in practice. Another experience he had had was that of a telephone wire having broken off, and the grass upon which the end fell had been set on fire by the sparking occasioned by the induced current.

M. ESBRAN then read a long communication, insisting particularly on the point that D.C. working must frequently be far less efficient than single-phase when the whole system from power-house to train was considered.

M. MAZEN, who is one of the engineers-in-chief of the Ouest-Etat railway, and is responsible for the electrical equipment, speaking again, said he wished to sum up the position from the point of view of the engineer who had to work the line. Single-phase working meant extra weight, and not only this, it meant that the apparatus took up more room on the motor coach, which was far more important. This was one of the reasons why he had continued to use D.C. He was not an opponent of single-phase traction; in fact, he had been one of the first to put in a single-phase equipment. The railway engineer must, however, take things as they are, and not as they would be in five or six years' time. The French railway system, taken as a whole, might be considered as a network of squares, each side of which was from 15 to 50 km. long. It was recognised that the correct policy for the railways was to obtain their current from an electricity works and not to generate it themselves—[M. Parodi concurred]—and the current offered to them was the one which was most useful for general application for the majority of purposes, viz., three-phase, 50-cycle. They had practically no option but to place sub-stations at the junctions of the network of squares, and under these conditions, and also after having carefully considered the London, Brighton & South Coast Railway system (with which company the Ouest-Etat railway was, of course, in close touch), they had come to the conclusion that single-phase working would not be so suitable for the conditions of their own railway as third-rail D.C.

Mr. DUDDELL (who occupied the chair at the Friday meeting) then thanked the speakers for their interesting communications. Speaking in French, he recalled the historical night in the early days of the single-phase 10,000-volt transmission from Deptford to London, when, owing to a cable breakdown, they had run for a night with earth return. The next morning they read in the newspapers of the remarkable "meteorological phenomenon" which had occurred during the night, and had interrupted all the telegraph circuits as far as Rome.

## Two Large Power Stations.

On Wednesday afternoon two of the large Paris power-houses were visited—the enormous station at St. Denis, and the so-called "Triphasé" at Asnières. Between them they supply a great part of the traction and lighting load of Paris, including the electric railways. Space will not permit of a complete description of these stations, but some of the interesting features may be mentioned. Both take their condensing water from the Seine; a feature of both is that some of the chimneys (two at St. Denis and one at Asnières) are of reinforced concrete; and both supply two-phase as well as three-phase current. The Seine water is comparatively clean compared to that of the Thames, and for filtering it a series of screens are used from 30 to 10 mm. mesh, which are simply raised up and cleaned by hand twice daily. The reinforced concrete chimneys are very elegant in appearance, and we were informed were 20 per cent. cheaper than brick chimneys, besides being quicker to erect.

At St. Denis there are 56 B. & W. marine-type boilers, and eleven Brown Boveri turbo-alternators with an aggregate capacity at normal rating of about 73,000 kw., and capable of dealing with heavy overloads. By the courtesy of the Compagnie Electro-mechanique, who supplied the Brown Boveri plant in

question, we are able to illustrate the largest of the generating sets below; it is a three-phase machine with a normal capacity of 11,000 kw. and an overload capacity of 15,000 kw. for half an hour, runs at 750 r.p.m., and generates at 10,250 volts, 25 cycles per sec. The two-phase pressure at St. Denis is 12,300 at the frequency of 41½ cycles (a legacy from earlier days). At this station an interesting bye-product is manufactured, viz., bricks for building purposes, which are made from the ashes. They have, we are informed, a strength of 140 kg. per sq. cm. The colour is dark grey, and there is said to be no difficulty in selling them at a good price. The brick-making plant includes four presses with a total possible output of 50,000 bricks per day. One thing that impressed the visitors at St. Denis was the exceedingly small number of workmen visible; the station seemed almost to run by itself. The total number of men employed there, we were told, is 85, including the repairing staff. The winter peak load at St. Denis is about 50,000 kw., and at Asnières about 25,000.

At Asnières the generating plant is partly driven by Corliss engines and partly by steam turbines, and is all made by the

station of the Gaumont synchronised cinematograph and gramophone.

#### Power Transmission on the Thury System.

On Thursday a Paper on this subject, by Mr. J. S. Highfield, was discussed. It is the third Paper which Mr. Highfield has written dealing with H.T.D.C. working, and for a description of the plant and system our readers may refer to *ELECTRICAL ENGINEERING* of June 13th, 1912. Mr. Highfield insisted that the H.T.D.C. series system should not be treated as a rival of the A.C. parallel system. When existing methods and standard apparatus offered a satisfactory commercial and technical solution to an engineering problem, there was no reason to depart from existing practice; but in problems where the cost of the transmission line was the most important element the continuous-current series system offered advantages. Among other uses for the constant-current system were those in which variable-speed motors were required, as, for instance, in mining work, as the constant-current series machine was capable of running at variable speeds with high efficiency and without

THE 11,000-KW. BROWN BOVERI TURBO-ALTERNATOR AT ST. DENIS.

Société Alsacienne, of Belfort. The two-phase plant is the more modern, but has, of necessity, the same unusual frequency of 41½ cycles per sec., as that at St. Denis. A 10,000-kw. two-phase turbo-alternator is being erected—probably the only machine of this size with this odd frequency. In this station we were shown two interesting two-phase-three-phase 1,500-kw. motor generators, a feature of which is that the stators can be rotated (by a small motor in the pit controlled from the switchboard) through an angle of about 5 degrees. This is rendered necessary in order that the machines can convert either from two-phase to three-phase, or *vice versa*; both are, of course, synchronous machines, and it is therefore necessary to have a means of adjusting the relative phases independently to synchronise with the other two- and three-phase plant running.

#### The Official Banquet.

Having feasted their guests with six of the best Papers ever read before their Society in the morning, and an inspection of one of the finest Continental power-houses in the afternoon, our hosts completed the day's programme in the evening on Wednesday by another feast, which demonstrated that the French *chef-de-cuisine* can still outdistance his imitators in any other country. M. Berthelot proposed our healths in an excellent after-dinner speech, in the course of which he alluded to the fact that one of the distinguished guests was Prof. Carey Foster, who, as President, had represented the Institution of Electrical Engineers in Paris at their first official visit in 1889, and Mr. Duddell responded with the toast of the Société Internationale des Electriciens. An entertainment followed, which included recitations by Madame Bartel, of the Comédie Française, dancers from the Opéra, and an interesting demon-

strated complicated regulators. Air compressors, for instance, could be driven with constant-current series motors without any regulating gear, for as the pressure rises the motor will slow down, and by giving the brushes the correct lead the motor can be arranged to stop when the pressure exceeds any predetermined limit. The only automatic safety devices used are a short-circuit switch, which closes automatically if the generators reverse their direction of rotation, due to a breakdown of the prime mover, and a slipping coupling, so that if a violent short circuit should pull up the dynamo, the flywheel effect of the moving parts of the steam engine would not get further than the coupling. The current is kept constant by a regulator, which may either vary the speed of the prime mover or the position of the brushes. The latter arrangement is used on Mr. Highfield's system at the Metropolitan Electric Supply Company's station, and was described in the article above alluded to. On the H.T.D.C. area supplied by this station, two single cables are used laid in cast-iron pipes. At a pressure of 100,000 volts they will carry 12,000 kw. In addition to the cables, provision is made for working with an earth return, and for considerable periods the whole of the power has been supplied from a single cable and the earth, so that the author considers that he has practically a duplicate 12,000-kw. line system. Needless to say, this maximum output has not been yet reached by a long way in the area in question.

The Author pointed out that it is easy to meet an increasing load by starting up new stations on the same line, and that this could be done without increasing the maximum line pressure by placing the additional stations at proper points in relation to the sub-stations. This has been done on the Chaux de Fonds system, which was started in 1896 with one

station, and as the load increased two more were erected. On this system the line current is 150 amperes, the total length of circuit 32.3 miles; there are seven machine units with a total output of 1,890 kw., and the total line pressure is 12,600 volts. More recently a similar method has been adopted on the Moutier-Lyons system. The difficulties of running stations in parallel are thus avoided, and the uniform section of cable renders the series system more flexible in this respect than the parallel.

Another advantage put forward by Mr. Highfield is that difficulties due to cable capacity and inductance are eliminated, and he contends that as a higher pressure can be used with continuous current than with A.C., the energy can be transmitted to a greater distance. In the case of overhead lines the author pointed out that the cost of an overhead three-phase line at even the same pressure is greater than that of a series continuous-current line, and for transmitting up to, say, 30,000 kw. not more than four wires will be required working two in parallel, instead of six wires for a similar three-phase line, so that there would be some saving in insulators. The weight of copper would in most cases, he contends, be less, as the regulation need not be so close, and the loss can be calculated purely on a commercial basis without reference to technical difficulties. The Paper included a list of the more important schemes in which the Thury system is employed, and a table showing the cost of overhead lines, bearing out his contention that the H.T.D.C. system is cheaper. In some instances the cost per kw.-mile of overhead line comes out greater than the cost of the underground continuous-current cable system.

In the power station Mr. Highfield considers that the maximum size of a generator on the H.T.D.C. system may be taken as 1,200 to 1,500 kw., so that to make up a large power unit it is necessary to couple two or more generators to a single prime mover. Line losses, the author admitted, would usually be higher than with the constant pressure system, and the A.C. system must also be given the advantage as regards the cost of the sub-stations, except in those cases in which the frequency of the transmission line is different from that required in the distributing circuits. In such a case as that which he had had to consider, in which a load of about 7,000 kilowatts had to be supplied at various points in a scattered district involving a length of approximately 100 miles by underground mains, and in which the cost of energy was comparatively small, the series system was the only one commercially possible.

#### DISCUSSION.

M. THURY said that he would commence by making a sort of confession of faith. He would admit that the applications of the H.T.D.C. system were limited. Constant potential remained the system for distribution, and A.C. transmission suited this in most cases. The series system came in for very long-distance transmission and when underground cables were desirable. An overhead line was dear, and its maintenance expensive when pressures were high. For distribution the series system was limited to cases in which there were only a few consumers of large size. It also enabled problems to be solved which would be impossible with A.C.; for instance, in crossing a small stretch of sea in an American installation, it had been adopted because the cable-makers would only give a guarantee in the case of single cable. Tests at Lyons and also in England showed that D.C. cables absorbed a negligible amount of energy, and this was confirmed by its being possible to test them with a small electrostatic machine. At Lyons it was found that a cable with only three millimetres thickness of insulation would stand 300,000 volts. He placed the limiting size of generator at a higher figure than Mr. Highfield, and referred to a scheme which he had recently got out involving the use of 5,000 kw. divided between two armatures. In conclusion, he thanked Mr. Highfield and stated that several of the accessory apparatus (some of which was described in the paper) and various improvements were largely due to Mr. Highfield.

In answer to a question by M. CLAUDE, M. THURY said that there were no electrolytic troubles in the cables, as by the process of manufacture there was no trace of moisture in them.

M. BOISSONOS described a special case in which several generating stations were wanted, and although it was possible to run them in parallel, yet it was deemed advisable to make use of the H.T.D.C. system. The arrangement decided upon ultimately was to have two lots of stations, three high-tension D.C., and three three-phase interconnected and working on to the same distributing network.

In reply to a question as to whether there had been electrolytic troubles owing to the earth return, Mr. HIGHFIELD said that they had been working in this manner for four months continuously, and there had been no interference with the track signalling on the Great Western Railway.

On the St. Maurice and Lausanne system, M. THURY said that iron earth-plates were used which should theoretically have been destroyed by electrolysis in less than two months, but which worked as well after a year as they did on the first day, owing to a protective film of oxide of iron having been formed. No electrolysis on pipes had been noticed, but he admitted that electrolysis is to be feared, and it was the first thing to be thought about in planning a system. If necessary one had to go one or two kilometres to find a place for an earth.

Mr. J. F. C. SNELL said that while simplifying the distribution system, the method complicated the generating system. The small size of units was one of the difficulties. On the question of cost he referred to a proposal made some time ago for supplying power for London from a station about 100 miles distant, viz., half-way to the coal fields. The cable would have cost £10 per kw. excluding wayleaves, and this represented 15s. per kw. demanded per annum. Assuming that the load-factor was equivalent to 2,628 units per annum per kw. demanded, this was equivalent to a charge of 0.07d. per unit for transmission. If the more favourable site of the generating station enabled the cost of the coal to be halved, so that about 7s. per ton was saved, the saving in annual costs would be 0.099d. per unit, and the extra complication would hardly be justified.

Mr. K. EDGUMBE, who spoke in French, said that on one occasion Mr. Mordey had said that an advantage of the A.C. system was that it was impossible to employ accumulators, and he gathered that Mr. Highfield thought one advantage of the H.T.D.C. system was that it was impossible to employ automatic circuit-breakers. On the other hand, it seemed that one of the objects of coupling two cables, as Mr. Highfield did, might be that one could be cut out automatically in case of a fault.

Mr. F. C. RAPHAEL asked if M. Thury could explain how it would be possible to continue the supply to a single line system if a serious earth occurred on the line, as might happen in the case of an underground cable. So far as he could see, the automatic regulator in the station would continue to maintain the current sent to the line at its regular constant value, no matter how large a proportion of it was leaking at the fault, and the result would be an enormous drop in pressure at the sub-stations and consumers connections.

M. THURY said he found it difficult to answer either Mr. Edgumbe or Mr. Raphael, as he had had practically no experience with faults on a line. He only recalled two cases in which he had had to shut down the generating station in consequence of them. He mentioned one other case in which a fault had been sufficient to set fire to the pole and burn it through, thus re-insulating the line, as the upper pole remained suspended in the air.

Mr. ROGER SMITH said that along either side of a railway there was a strip of land, but there was frequently a difficulty in carrying a three-phase line along it owing to its narrowness. He pointed out that 1,200 kw., the largest size of unit mentioned by Mr. Highfield, was about the power needed for an average-size goods train, and that this would be a suitable unit for sub-station motor-generators on a railway system. Mr. Highfield's earth return current, he said, had been flowing for months under the Great Western Railway, where earth returns were used for the signalling, and where telephones were worked at a pressure of only two volts, and no trouble had been experienced. He was impressed by the simplicity of the sub-station arrangements. Adjoining some of the sub-stations there were allotments, so well kept that he thought the attendants were able to work more in the garden than in the sub-station.

Mr. B. M. JENKIN said that the great advantage in this system was that the cable was all of one section, which facilitated extensions. He was also struck by the great simplicity of the switchboard, for the switching off of large current was becoming a serious difficulty.

M. MAURICE LEBLANC then read a Paper on "Three-Phase Current." This was a long review of present practice and recent developments, and was read from manuscript. The Paper is reserved for publication in the Bulletin of the Société Internationale des Electriciens. There was no discussion.

#### Visit to the Tramway and Railway Depots, &c.

The dépôt of the Compagnie Générale des Omnibus de Paris is far more than an omnibus dépôt and repair shop; the company also runs the tramways in Paris, and manufactures its own cars. The dépôt and works cover an area of about 96,000 sq. metres, and employ 2,000 people. The actual manufacturing part of the works is extremely busy at present, as the existing electric tramway system is being rapidly developed. In passing, we may mention that in some cases trains of three cars are to be used in the rush hours, the middle car a trailer, and the first and last motor-cars. Another interesting point mentioned to us is that large use is being made of aluminium feeders for the tramways. After a visit to these shops, every department of which was shown, the party proceeded to the dépôt and shops of the Métropolitain railway, then to those of the Nord-Sud Railway, and finally to one of the Nord-Sud sub-stations. The Nord-Sud Railway runs in shallow tunnel from north to south of Paris, connecting with the Métropolitain at a few stations. Its equipment differs from the Métropolitain in being on the three-wire system, partly three-rail and partly trolley. The overhead wire is connected to one side of the three-wire network, and the third rail to the other. Two four-motor cars are used, one at the front, and one at the back of each train. The front one takes current from the trolley wire through a special form of collector, and the back one from the third rail, so that the two sides of the network are balanced by each train.

### The Eiffel Tower and its Time Signals.

On Thursday M. Eiffel held a reception on the Eiffel tower; the wireless installation and time-signalling system there was shown to the visitors, and on Saturday a lecture on the latter was given by Commandant FERRIÉ, who was responsible for the installation. In the wireless installation itself a recent innovation is an alteration in the form of spark gap employed. Instead of the spark occurring between two zinc rollers, the discharge is now made between a copper tube and copper plate, and air is forced through the tube by a blower.

The Eiffel tower wireless installation is chiefly used for naval and military purposes, for the time signals, and to send reports as to the force of the wind, which are useful for aeronautical purposes in the northern half of France. Reports are received from Reykiavik (Iceland), Valentia (Ireland), Ouessant (France), Corunna (Spain), Horta (Azores), and St. Pierre et Miquelon (North America), and these are sent out from the tower daily after the time-signals have been sent.

The international wireless time-signal, chiefly of use to enable ships to check their chronometers for observations of longitude, but also available for business purposes and the general public, is sent out twice daily: three signals at 10.45, 10.47, and 10.49 a.m., and three at 11.45, 11.47, and 11.49 p.m. At one minute before these times a series of dashes are sent out by a simple Morse hand key for 50 seconds as a warning signal, and then, after an interval of 10 seconds, there is a single dot, indicating the exact time.

A special clock (which is compared with the master clock in the observatory a short time before the sending out of the signals) is provided with an electric contact which is closed automatically for a quarter of a second to give the final time-signal. This contact is connected by an underground cable to a relay controlling the transmitter in the wireless station at the Eiffel Tower. The lag due to the mechanical and electrical inertia of the various apparatus is carefully measured periodically, and allowance is made for it. From July 1st onwards there will be some alteration in the times for sending out these signals, and also in the character and sequence of the warning signals. The times at which the exact time-signal will be sent will then be 10 a.m. and midnight.

It may be mentioned that considerable use is made of these time-signals by ordinary clock-makers in Paris. In view of the great power of the Eiffel Tower signals, only the simplest form of receiving apparatus and aerial are necessary; in fact, the telephone wire or even gutters, or the iron balustrade of a balcony, are found sufficient.

Before the ordinary night signals, the Eiffel Tower sends out a series of 180 short dots regularly spaced at one second less about 1.50th of a second apart. In each series the 60th and 120th dots are omitted in order to facilitate counting by the observers. This series of dots is received by the wireless installations of the Paris Observatory and by other observatories, where the operator listens simultaneously to the beats of another clock or seconds chronometer. The two sets of beats and dots constitute an "acoustic vernier." By noting the moment of coincidence and the previous number of the "wireless" beats, even greater accuracy of observation is possible than that of the astronomical observations of time themselves.

### The Neon Light.

Another lecture, given on Saturday morning, was on luminescent neon tubes, by M. Georges Claude. An electrical discharge passes easily through neon; the ratio of the voltages required for a discharge across the same distance in air and neon respectively is 100:15. Unfortunately, however, the neon spectrum contains no blue lines at all. Another difficulty is that impurities escaping from the electrodes will prevent the neon from being set into luminous vibration. M. Claude overcomes this latter trouble by using Dewar's method of purifying neon by means of charcoal cooled by liquid air, which he applies in the tube itself to remove the impurities. It is also necessary to give the electrodes a large surface to prevent any volatilisation of them, as otherwise the neon tube has a short life. Taking these precautions, M. Claude has succeeded in obtaining a life beyond that of incandescent lamps. Compared with the Moore tube, the voltage required is only about one-third, and the candle-power is greater. Moreover, the efficiency is better, being 0.6 watt per candle instead of 1.7.

To overcome the red light, neon tubes and mercury vapour tubes are used in conjunction. Here another difficulty occurs, namely, that while neon tubes require high-tension alternating current, Cooper-Hewitt tubes require low-tension continuous current. In place of ordinary mercury vapour, M. Claude uses in his "correcting" tubes neon and some mercury. He did not explain why this should render them suitable for alternating current, but he asserted that they could be used next to the neon tubes, and with the same current, and the combination would then give an illumination of an agreeable colour at 0.8 to 0.9 watt per candle.

### Levelling the Load Curve of Telephone Operators.

Mr. Slingo's Paper on "Application of Mechanical Devices to the Assistance of Manual Operating in Telephone Exchanges" was also taken on Saturday. A system of traffic distributors is being put in at the Paddington exchange in

London for the purpose of levelling the load of the operators at the subscribers' boards. In ordinary circumstances the operator, even during the busy hour, must have a fairly large percentage of unoccupied time, in order that she may be able to cope with the traffic during the short rush periods, and, of course, during the slack hours the load efficiency per position is considerably reduced. The object of the traffic distributor is to place a subscriber automatically into connection with any idle operator directly he lifts his receiver. In the experimental arrangement which is being installed at Paddington, the existing lamps and jacks individual to the subscribers on each position are being replaced by others, say from ten to twenty in number, common to the traffic distributing apparatus. Each position will only be able to receive one call at a time, i.e., whilst an operator is answering one call, one more glow can be received, and any further traffic will be automatically passed to other positions. A difficulty, of course, arises if several types of service are in force at the same exchange, and, to meet this, a separate section of the traffic-distributing apparatus will have to be reserved for each type of service. If the scheme proves satisfactory, it is proposed, in future installations, to arrange that the traffic distributor will pass the call direct to the answering side of the cord circuit, so that no answering jack will be required.

Much difficulty has been experienced during recent years in large cities owing to the poor transmission conditions involved when several underground call-wires are connected to the same "B," or junction, position. It is proposed to instal experimentally a simple automatic call-seeking device which will enable one call-wire at a time to have access to the "B" operator. It will be arranged so that the "B" operator can trip the apparatus in order that only one call can be passed by a particular exchange before the other exchanges working to the same position have each had an opportunity of passing a call. The "B" operator will be made aware of the necessity for using this tripping apparatus by the glowing of a lamp on her position, which will indicate the fact that an outlying exchange wishes to pass a call. By giving improved transmission it is expected that quicker operating will result, with comparative immunity from "wrong numbers."

An automatic call-wire selecting equipment has been installed at the "Central" exchange in London for the purpose of facilitating working on the call wire between the "A" and "B" boards. The object is to avoid confusion during busy periods owing to one operator interrupting another, and also to prevent the delay occasionally experienced by the "A" operator in finding a slack call wire. The selecting device will select and isolate a call wire when one is required by an "A" operator. There are ten call wires in the group affected, and they were, before the introduction of the new conditions, operated from ten call-wire keys, the circuits of which were multiplied over 160 "A" positions. When the selecting equipment was introduced, the ten keys per position were replaced by one key per position. Each operator is given a selector, which rotates when she depresses her call-wire key, and the rotation continues until the wipers of the selector find an idle "B" operator, when the "A" operator is able to pass a call. Thus, when the "A" operator depresses her call-wire key, she is automatically connected to a disengaged "B" operator, and she hears a click in her receiver as soon as the disengaged call wire is obtained. Only one "A" operator can obtain connection with the same "B" operator at the same time. A lamp placed on the chief supervisor's desk glows when all the accessible "B" positions are simultaneously engaged with traffic passing over the call wires. This indicates that there must be delay owing to the "A" operators having to wait to find a free "B" operator, and that therefore additional "B" positions should be staffed to cope with the traffic.

The equipments described above were installed for the British Post Office by Siemens Bros. and Co., Ltd.

Mr. G. H. Nash (Chief Engineer of the Western Electric Co.) alluded to the difficulty of differentiating between the different kinds of service mentioned by Mr. Slingo in the first part of his paper, as, of course, it is an inherent property of the system that the operator does not know who is the calling subscriber. To make provision for this, he proposes that a lamp board should be installed on a wall in the exchange clearly visible, upon which the necessary information would be automatically lighted up. In addition to the advantages indicated by Mr. Slingo, Mr. Nash pointed out that the operator should save about one second per call when the traffic distributor is employed, and that, in consequence, the equipment of the operator's position might be increased by three or four cord circuits. The next step would be, of course, to wipe out the multiple altogether.

This closed the business part of the meeting. On Saturday afternoon an excursion was made to Versailles, the Trianon, and the Buc aerodrome, and the more energetic members of the party were also enabled to inspect the new electrical carriages of the Ouest-Etat Railway—already referred to in M. Mazen's Paper and remarks in the earlier part of our report—on the way back. On Friday afternoon there was also a most enjoyable excursion to Chantilly.

# QUESTIONS AND ANSWERS BY PRACTICAL MEN

## RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

## QUESTION No. 1,340.

Please show how an ordinary incandescent lamp could be connected to a 25-h.p., 220-volt, compound-wound, D.C. motor circuit, to act as a signal at a distant point, in the event of the motor ceasing to run by any cause.—"SIGNAL."  
(Replies must be received not later than first post June 5th.)

## ANSWERS TO No. 1,339.

From an E.H.T. three-phase supply, with static transformers, three phase, six-phase primary delta connected, secondary star connected, it is required to take a large amount of power—single-phase L.T. and H.T.—without unbalancing the three-phase supply. What is the best way to do this, and is it possible without using rotating machinery? Also, could a small amount of single-phase power be taken without using rotating machinery, and, if so, how much? What is the effect of unbalancing a three-phase circuit?—"TRANSFORMER."

The first award (10s.) is made to "ALPH" for the following reply:—

Various schemes have been proposed to give single-phase power from a three-phase supply without unbalancing the latter, but since the total power supplied by a balanced three-phase circuit is steady, while that taken by a single-phase circuit varies from zero to a maximum twice in every cycle, it is evident that the apparatus used to transform from one to the other must be capable of storing energy during that part of the cycle when the single-phase power is less than the mean value, and giving up the stored energy when the single-phase power required is above the mean value. Since a transformer is incapable of storing energy and equalising the demand in this manner, it is impossible to draw single-phase power from a three-phase circuit without unbalancing the latter, by any system of transformer connections. If a large amount of single-phase power is required, it will be necessary to instal a motor-generator set to avoid serious unbalancing, and the best and cheapest arrangement would be a squirrel-cage induction motor wound (if possible) for the full supply voltage, driving a single-phase generator wound for the required H.T. single-phase voltage, and stepping down to the L.T. single-phase voltage by means of static transformers where required. If the bulk of the single-phase demand is L.T., it might be preferable to use a three-unit set, consisting of an induction motor driving two generators, one for each voltage, or even to generate all the single-phase power at the lower tension, and step up to H.T. where required, if the amount of H.T. power required is so small that the extra cost of the cables to carry the heavier current is negligible. If approximately the same amount of power is required, H.T. and L.T., the cheapest plan would be to wind the generator as a two-phase four-wire machine, winding one phase for each voltage. This would have the disadvantage of not permitting independent voltage regulation on the two circuits. Without further particulars of the maximum single-phase demand, the capacity of the power station, &c., it is impossible to say whether a motor-generator set will be required. The effect of unbalancing a three-phase circuit is that the phase voltages are no longer equal and 120° apart as they are in a balanced circuit. The neutral is thus displaced, and, under certain conditions, heavy circulating currents will be induced. The regulation and operation of the generators and other apparatus connected to the line will also be adversely affected, while, since the single-

phase current will not be equally distributed between the different phase windings of the generators, &c., local heating in the coils carrying most current will become excessive before the machines as a whole are carrying their full rated load. A small amount of single-phase power can be taken from the line without causing trouble, but the exact amount can only be determined by careful consideration of the circumstances of the particular case, and it is impossible to give any general figure which would be of practical use. Since both H.T. and L.T. single-phase power are required, in this case it would seem to be possible to subdivide the single-phase supply into two or possibly three groups, connecting each to a different phase of the three-phase supply. In this way the maximum unbalanced demand on any one phase would be only a fraction of the total single-phase load, and this would only occur when one section was running alone. When all the sections were running, the load would be largely balanced. In any case, if it is decided to take off the single-phase supply by means of transformers, the best connection is undoubtedly the simple one of a single-phase transformer connected across two of the supply lines. This has the great advantage that the whole of the transformer capacity is utilised, i.e., if the single-phase current required is  $I$  at a voltage  $E$ , the K.V.A. rating of the transformer is  $E \times I$ . In all the other schemes which have been proposed, the capacity of the transformers required is greater than this (up to twice as much in some cases). The capacity of the leads between generator and transformer is no greater in this scheme than in any other, and is less than in some, while the heating of the generator also is no worse than in any of the other schemes. In fact, no scheme of connections has yet been devised which has advantages to justify its adoption in place of the simple single-phase transformer, with the possible exception of a method recently published in the technical press, (see ELECTRICAL ENGINEERING, Vol. VIII., p. 448, August 8th, 1912), which claims to give single-phase current of triple frequency without unbalancing the three-phase supply. The writer is not aware, however, that this method has been developed on a commercial scale, and in any case it would hardly appear to be suitable for supplying a large amount of power, since it is based upon distorting the wave shape by using transformers with highly saturated cores, and utilising the third harmonic thus produced. It may be mentioned in passing that in a three-phase generator which is required to supply some single-phase current, the active material is used to rather more advantage if the machine is delta-connected than if it is Y-connected. In the former case one phase carries two-thirds of the single-phase current, and the other two phases in series carry one-third. In the latter case two of the phases carry the full single-phase current, and the third phase carries none. The unbalancing and local heating is obviously less in the case of the delta-connected machine.

The second award (5s.) is made to E. B. Pansey, who writes as follows:—

Two methods of connecting up the three-phase to six-phase transformers so as to obtain a single-phase supply without

Fig. 1.

Fig. 2.

Fig. 3.

unbalancing the three-phase system are shown in the accompanying diagrams. In Fig. 1 the two halves of each phase are connected in series, so as to convert the six-phase secondary into a three-phase one. The three phases are connected up

somewhat similarly to a delta connection, but that one phase is reversed and the delta is left open. From the open ends of the delta, A, B, a single-phase supply may be taken. If the volts per phase of the secondary be called  $v$ , the voltage between A and B will be  $2v$ . This is shown in the vector diagram, Fig. 2. In this diagram OA, OB, and OC represent to scale the volts per phase of the secondary, OC being the voltage of the reversed phase. It will be found that the resultant of OA and OB will coincide with OC; therefore if OC be produced to D, making CD equal to OC, OD will be the resultant of the three vectors, and it will represent to scale the voltage between A and B. Therefore the voltage between A and B will be twice that of each phase. In Fig. 3 a similar arrangement is shown to Fig. 1, but in this case the halves of the secondaries are connected together in parallel instead of in series. The effect of this is that the volts on the single-phase mains are half what they were in the former case. Otherwise the action is the same as in the first case. Should neither of these arrangements give the desired voltage, a phase-changer must be used, say, a three-phase motor driving a single-phase generator. Another way would be to rewind the present transformers so as to get the required ratio. A third way would be to use a second transformer, the primary of which would be connected to the secondary of the existing one. Single-phase could be taken from one phase of the three-phase system. The capacity of each phase is fixed, independently of the balance of the system; and one phase could be loaded right up, even if the others carried no load whatever. The effect of doing this would be to cause an extra drop of volts in the heavily loaded phase; and also in the others, if the load is inductive, due to the demagnetising effect of a lagging current on the generators. The efficiency and capacity of the system would also be reduced in proportion to the amount of out-of-balance load.

### A NEW METHOD OF OBSCURING LAMPS

A NEW lamp obscurer has recently been placed on the market by Siemens Bros. Dynamo Works, Ltd., incandescent lamp and fittings department, Tyssen Street, Dalston, N.E. Hitherto the only method of obscuring lamps apart from the use of varnishes was by means of sand blasting, a process which is somewhat expensive, and in which breakages are likely to occur. The Siemens obscurer is a fluid which etches the glass leaving an even matt surface. Its application is extremely simple, the acid being simply poured into a container sufficiently large to take the lamp or any glass article it is desired to obscure. The surface of the glass should, in the first place, be dusted to ensure that it is free from dirt and grease, and then immersed in the acid for a period of from four to ten seconds. It has then only to drain for about a minute, and afterwards thoroughly washed to remove all traces of milky film from the glass. It can then be dried off with a clean cloth and the operation is complete. Heating is not at all necessary, either in the case of the article to be obscured or of the obscurer. Neither is it necessary to place the lamps on circuit during the operation. From a sample piece of glass obscured by the process we can bear witness as to the fineness and evenness of the effect. The fluid is supplied in sealed kegs or earthenware jars at 28s. per gallon or 7s. 6d. per quart.

### CATALOGUES, PAMPHLETS, &c., RECEIVED

**FANS.**—The small energy consumption combined with the low prices at which electric fans are now obtainable should enable everyone to provide a cooling breeze when nature is at fault, as has been the case recently. A special supplementary list of table, oscillating, ceiling, and porthole fans for D.C. or A.C. is now being circulated by Scholey & Co., Ltd. (151 Queen Victoria Street, E.C.). To increase further the air displacement, we note that Pitters' Patent Multiblades can be fitted to several of the designs at a slight extra cost.

*Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."*

**TELEPHONES.**—A neat folding card from the Sterling Telephone & Electric Co., Ltd. (200 Upper Thames Street, E.C.) describes their "Ferro-case" battery ringing telephones.

**INSULATION TESTERS.**—The Electrical Engineering & Equipment Co., Ltd. (109-111 New Oxford Street), send us some particulars of the latest form of their "Mego-meter" insulation testing set with self-contained generator. This apparatus embodies various electrical and mechanical improvements, but is

in its essentials the same instrument which was described in *ELECTRICAL ENGINEERING*, Feb. 22nd, 1912, page 83.

**GEARING.**—An illustrated pamphlet from the Power Plant Co., Ltd. (West Drayton, Middlesex), gives particulars of a combined driving, starting, and roll-turning gear for cold rolls. The main gear is of the double helical type, and a helical back gear is provided which is used when starting or for roll turning, but disengages automatically when the through drive from the motor is put into action.

### WATER-TIGHT GLANDS FOR BULKHEADS

THE numerous cables, telephone, signalling, and other wires which have to pass through bulkheads on warships and other vessels demand glands which, while preventing the passage of water, will not injure the insulation of the cables, &c. A new method has been designed by Mr. T. Harden, and has been approved and adopted by the Admiralty, and which, by the courtesy of The Metal Jointing Co., Ltd., of Adelphi House, W.C., we are able to describe. By this system it becomes possible to dispense entirely with packing, and to relieve all pressure from the lead sheathing, which is ill-adapted to stand it. A gland consisting of a cup and back nuts is used, which bear upon a hemisphere of lead cast on to the lead covering of the cable. In the case of the larger cables, this cup and nut form the actual mould, and the lead is cast on in place. The fitting is shown in Fig. 1. This casting on is rendered possible without any special precautions by covering the cable first with the Company's special alloy used in all their metal jointing processes, and called "Amalgaline." The cable having been fixed in position—rove through the glands and bulkheads—a strip of "Amalgaline" is wrapped round the lead covering of the cable on the part which enters the gland, the back nut is

FIG. 1.—BULKHEAD FITTING WITH CABLE DRAWN OUT TO SHOW PIECE CAST ON. FIG. 2.—SMALLER GLAND FOR SWITCH-BOXES, &c.

screwed up until the pouring holes are vertical, molten lead is poured in, and a half-sphere or ball is cast upon the lead covering of the cable, as is shown in Fig. 1; one turn of the back nut cuts off the runner, and the gland is completed. No matter how much strain is brought to bear upon the nut in tightening, the effect upon the lead covering is nil; the pressure is solely upon the casting, which can only compress tighter and tighter to the cup. We are informed that these glands have been subjected to enormous stresses by hydraulic pressure, and the cables, after casting numerous spheres upon the lead covering, have likewise been subjected to both pressure and insulation tests without a single fault developing. With small cables or wires for such purposes as telephone or lamp wires, a separate mould is used. These, of course, are more flexible and readily got at, but in the case of cables passing through bulkheads, &c., these are practically immovable. A gland for this purpose is shown in section in Fig. 2. The introduction of these glands would appear to have overcome a great difficulty that continually confronted both mechanical and electrical engineers dealing with marine work and has created a demand for glands on the same principle for numerous requirements both ashore and afloat. The Company have in hand double glands for tightening from either side of the bulkhead, oval glands, and numerous other arrangements.

**Osram Lamp Patents.**—An order in the usual form was granted to the Osram Lamp Works, Ltd., on Friday last, in the High Court of Justice, Chancery Division, by Mr. Justice Neville, against Louis Schloss & Co., for the delivery up of all metal filament lamps infringing the Osram patents and for an inquiry into damages.

On page 156 of our issue of March 13th we referred to an interim injunction restraining L. Apple, 13 Brewer Street, Regent Street, W. (Brewer Lamps), from selling lamps infringing Osram Patents Nos. 23,899 of 1904, and 18,622 of 1906. On Tuesday, before Mr. Justice Warrington, the Osram Lamp Works, Ltd., were granted a perpetual injunction, with costs, and an inquiry as to damages, &c., the defendants not having entered any defence to the action.

## REVISION OF THE BOARD OF TRADE REGULATIONS FOR OVERHEAD WIRES

A REVISED set of model regulations for high-pressure overhead wires is being issued by the Board of Trade, which embodies some alteration in the previous codes. A revised memorandum for the guidance of applicants for consent to overhead schemes has also been issued. The general idea is that the applicant must set out certain statements relating to the particular scheme, including the working voltage; the kind of wire, whether copper or aluminium, solid or stranded, its sectional area, tensile strength and elongation; the average and maximum length of span; the minimum height of the wires from the ground; and the name or description of any automatic protective device that is used, and must submit maps (on the six-inch Ordnance scale) and drawings of construction. Regulations are then "made" for each case separately, after consideration of the circumstances, following the model codes, unless special alterations are sanctioned.

Among the changes in the regulations we notice the reduction of the wind-pressure from 30 to 25 lb. per sq. ft. It may be remarked that this is more favourable than the German regulations, for no allowance is made for accumulation of snow or ice, and it is the maximum allowance, while in Germany 125 kg. per sq. mile. (256 lb. per sq. ft.) is the usual allowance, and this may be increased near the sea or in other places specially exposed to the wind.

A new regulation appears in the high-pressure code requiring precautions to be taken against accident due to contact between a wire and a tree. In other countries it is usual to clear away trees on each side of a transmission line, but rights of way are so difficult to obtain here that this is often impracticable. Another new regulation prohibits the carrying of high-pressure wires across the premises of a consumer except under special conditions. This regulation avoids the difficulty that such wires might be regarded by the Home Office as service wires, and therefore excluded from the Factory Regulations. As the code is really intended only for cross-country work, responsibility for accident might fall on the supply company.

With regard to the important question of earth wires, the alternatives are offered of a continuous earth wire carried from pole to pole, or the ironwork on each pole being connected to a substantial earth-plate. We are glad to see that the method of crossing roads is not prescribed, and that it is left to the applicant to propose details for approval. Wire cradles have been abandoned for some years, and one of the recent codes suggested the strengthening of the weakest points by the duplication of the insulators and the use of a supplementary conductor wire reaching three or four feet in both directions and securely whipped or clamped to the main wire. Sometimes the supplementary wire is carried across the road if the span is short. Several improvements and some new departures in guarding against the fall of wires have been devised lately. Opportunity is given for the adoption and development of these by the details being left open.

## ELECTRIC TRACTION NOTES

A report of an interesting discussion on electric traction at the Paris Meeting of the Institution of Electrical Engineers will be found on pages 299 to 303.

The Loetschberg Tunnel is to be opened for traffic on June 1st. Apart from its interest as a 9-mile tunnel driven in quick time under difficult conditions, and its importance from a traffic and possibly even from a strategic point of view, it marks a step in the history of electric traction as practically the first application of the 15-cycle 15,000-volt single-phase system for really heavy work. The traffic will be worked by electric locomotives, and extensive trials have been made on the Spiez Frutigen approach line to the tunnel of locomotives made by the Siemens-Schuckert, Oerlikon, and A.E.G. Cos.,

the result of which was that ten of the Oerlikon type were ordered, half of which will actually be built by Brown, Boveri and Co. This pattern of locomotive was fully described in *ELECTRICAL ENGINEERING*, Vol. VII., p. 18 (Jan 12th, 1911), and its general arrangement is shown in the accompanying figure. The two motors, one on each truck, each develop from 1,000 to 1,250 h.p. and drive through helical gearing and connecting rods. The locomotive complete weighs 108 tons, and

is designed for a maximum speed of forty-six miles per hour and a maximum draw bar pull of 28,400 lb. Power is obtained from two power stations on opposite sides of the tunnel belonging to different companies.

In the House of Commons on Tuesday a discussion took place on a motion by Mr. H. Lawson (Mile End), that the introduction of trolley-buses in London by the L.C.C. shall be subject to the veto of the borough councils, in the same way as tramways are. The Board of Trade opposed the motion, but it was eventually passed by a majority of 79.

## TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

Our report of the Proceedings of the Joint Meeting of the British and French Institutions of Electrical Engineers in Paris last week contains, on p. 306, descriptions of the wireless time-signalling arrangements on the Eiffel Tower, and also a Paper by Mr. W. Slingo on some new automatic traffic distributing devices which are being installed in London telephone exchanges.

The much-talked-of criminal libel action by Mr. Godfrey Isaacs, Managing Director of Marconi's Wireless Telegraph Co., against Mr. Cecil Chesterton, Editor of the *New Witness*, commenced at the Old Bailey on Tuesday. The statements complained of were in connection with the Imperial wireless telegraph scheme, Mr. Godfrey Isaacs alleging that these amount to a charge of conspiracy with his brother, the Attorney-General, to secure the contract by undue influence.

Another matter of considerable interest in connection with the Marconi Co. is the announcement of the issue of a writ on behalf of some of the shareholders against the directors of the English Co. to recover a sum of about £1,000,000, said to be the difference between the sale price and par value of 500,000 shares with the American Marconi Co., presumably held by the English Co.

The United States Government has placed an order for a Poulsen wireless telegraph station at Colon, and according to a statement in *The Times* the day and night range is to be 3,000 miles. We understand that a patent infringement action has been pending between the Marconi Co. and the American Poulsen Co. for some time, and that in consequence of this contract having been awarded the hearing of the action will be expedited.

The Canadian Government has concluded a contract with the Marconi Co. for the erection of wireless telegraph stations at La Pas (Manitoba) and Port Nelson (Hudson Bay).

Communications with Quillengues and Caconda were restored on the 23rd inst., as well as the Fao route.—Until further notice telegrams to Derna and Tobruk are sent by post from Bengasi.—Telegraphic correspondence to Morocco is now no longer subject to delay.

## "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

### Specifications Published May 22, 1913

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

7,903/12. **Pupin Loaded Lines.** F. A. BECKER. To regulate the attenuation in telephone and telegraph lines according to the different frequencies, inductances are inserted at equal distances. They are specially arranged compound shunts, which may be tuned to different frequencies. Four figures.

9,941/12. **Metal Filaments.** F. HANSEN and W. F. MOHR. To increase the specific resistance, tungsten oxide is converted into trioxide, to which is added boric acid-anhydride to saturation. This is then dried and heated in a neutral atmosphere, and reduced by heating with zinc powder. The zinc is removed, and is made into a paste and squirted.

10,655/12. **Induction Motors.** SUBMERSIBLE & J.-L. MOTORS and H. B. POYNTER. Insulation is eliminated from the stator, or else thin refractory layers only are used. Also the number of conductors is reduced as much as possible, and these are fed at low pressure through a transformer which may be incorporated in the base of the motor. To minimise leakage the laminations are enamelled, cut radially, and assembled so that the cuts are not continuous. The motors may be used under water if the pressure is kept below that at which electrolysis takes place. Four figures.

10,765/12. **Heating Element.** E. & O.A. Co., J. D. MORRISON, and L. H. DAVIES. The resistor is wound on a single triangular refractory insulator, so that the area of the front is the greater. Concave heat-reflecting surfaces are provided, and terminals are fixed to the flat ends. Seven figures.

10,863/12. **Wireless Telegraphy.** R. C. GALLETT. The transmitting aerial is slowly charged and impulsively discharged by quenched sparks in one sense only. Free oscillations in the receiving aerial are prevented, and only uni-directional currents flow. Two figures.

14,015/12. **Wireless Telegraphy.** W. DUBILIER. To produce small alternating currents of suitable frequency, e.g., 200 watts at 400 cycles, a primary oscillating circuit with a natural frequency equal to or an harmonic of the frequency of the oscillator itself, feeds another circuit through a transformer and including a spark gap, the aerial, and earth connection. Three figures.

16,153/12. **Cable Sheathing.** W.E. Co. (W.E. Co., U.S.A.). To decrease the cost of cable sheaths, an alloy of approximately 99 per cent. lead and 1 per cent. antimony is used. The alloy is preferably formed by combining the metals after they have been reduced to their natural state.

23,734/12. **Wireless Telegraphy.** R. GOLDSCHMIDT. High-frequency undamped waves are at the receiving station transformed to waves of constant low frequency by asynchronously rotating commutators. Six figures.

### Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

**Arc Lamps:** MASCHINEN UND METALL INDUSTRIE [Economisers for multiple arcs] 11,842/12; ROGERS and ROWE [Non-shunt arcs] 28,627/12.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** SIEMENS-SCHUCKERT [Regulation of frequency produced by polyphase induction generators] 8,070/12; DALEN [Railway carriage lighting] 10,993/12; W.E. Co. (W.E. Co., U.S.A.) [Lead alloys for tapes] 25,090/12; LAWTON [Apparatus for forming joint ends on conduits] 27,510/12.

**Dynamos and Motors:** GEORGE POLKEY, LTD. [Dynamos] 22,500/12; SIEMENS-SCHUCKERT [Field magnets] 3,627/13.

**Electrometallurgy and Electrochemistry:** STROHMENGER [Arc welding] 11,079/12; DEKKER [Electrolytes] 17,836/12; JÖSSINGFORD MFG. Co. [Arc furnaces] 26,165/12; [Tilting mechanism] 26,166/12; HARKER and SCOTT [Furnaces for fixing nitrogen from the air] 866/13.

**Heating and Cooking:** GUALTIEROTTI [Moulding silicon and its alloys for resistances and heaters] 10,657/12; COLLINS [Self-contained utensils] 18,911/12.

**Incandescent Lamps:** J. STONE & Co. and MYERS [Also lamp-holders] 10,959/12; JOLY, 20,361/12; SIDON, 27,813/12.

**Instruments and Meters:** ARTHORPE and CAMBRIDGE INST. Co. [Moving coil instruments] 11,279/12.

**Storage Batteries:** PORSCHE and ACHENBACH [Negative electrodes for alkaline cells] 29,848/12.

**Switchgear, Fuses, and Fittings:** HALE [Lamp-holders] 7,552/12; PERL [Switches] 11,051/12; THOMPSON (*Ateliers de Constr. Elec. de Charleroi*) [Remote control] 11,537/12; WANK-MULLER [Lamp-holders] 14,750/12; B.T.-H. Co. (*G.E. Co., U.S.A.*) [Sealing leading-in cables] 15,342/12; BOUTARD [Liquid resistances] 3,855/13.

**Telephony and Telegraphy:** POSSOLO [Ship and shore communication] 10,701/12; BARON (*Heimann*) [Graded service automatic telephone system] 11,261/12; ZAHARIA and ROTHLANDER [Wireless receiving stations] 12,444/12; SEFTON-JONES (*Drahtlose Telegraphie*) [Production of high frequency currents] 14,390/12; TELEPHON APPARAT FABRIK E. ZWIETUSCH & Co. Ges. [Selector switches] 16,151/12; PRANCE [Loud-speaking attachment] 17,357/12; SCHAEFER [Sourdines or dampers for conductors] 25,449/12; SIEMENS BROS. and PERRY [Insulating sectional iron masts] 1,899/13; SABULKA [Wireless transmitters] 6,479/13.

**Traction:** STUART [Railways] 2,957/12; HAYWARD [Railways and tramways] 10,417/12; ROTTENBURG and NEW TRANSPORT Co. [Setting selective control on moving automatic goods conveyor from a fixed station] 11,681/12; STUART [Signalling] 3,588/13.

**Miscellaneous:** HOLMES and KEMP-WELCH [Two separate and opposite drives from a single motor] 14,560/12; SIEMENS DYNAMO WORKS and CALLOW [Photometers] 15,660/12; KIRK and BAKER [Fire-alarms] 15,676/12; BRUCKMANN [Electricity charging calculator] 21,446/12; KILBURN [Vehicular tail light frontal indicators] 27,707/12; MOLLER and KONIG [Cooling incandescent wire] 27,950/12.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Distributing Systems, &c.:** CREIGHTON [Circuit protective gear] 5,662/13.

**Dynamos and Transformers:** A.E.G. [Windings] 10,608/13.

**Electrometallurgy:** HELFENSTEIN ELEKTRO-OFEN-GES. [Enclosed furnaces with upper charging chutes] 9,590/13.

**Heating:** ARPIN [Radiators] 10,289/13; [Bath water heaters] 10,403/13.

**Meters:** SCHÖLLER, 24,954/12.

**Switchgear:** A.E.G. [Immersed break] 10,077/13.

**Telephony and Telegraphy:** CEREROTANI [Printing telegraphs] 9,833/13; UDE [Telephone fixtures] 10,556/13.

The following Amended Specifications may now be obtained.

20,107/11. **Telegraph Receivers.** W. S. STELJES.

26,184/11. **Combined Oil and Electric Furnaces.** V. STOBIE.

### Application for Amendment

1,950/08. **Telephone Switch Hooks.** J. E. KINGSBURY. Removable arms are arranged so that the stem engages with the parts within the case without it being opened, and cannot be again withdrawn without the case being opened. The W.E. Co. are now seeking leave to amend by striking out claim 1, which broadly covers switch hooks which may be inserted or removed from the case without tools. The subject-matter is said to have been old when the application was filed.

### Petition for Extension of Term of Patent

24,048/99. **Telautographs.** F. RITCHIE. Constructional details and arrangement of apparatus. The National Telewriter Co. intend to apply on July 1st to Mr. Justice Warrington for a date to be fixed for the petition to be heard. Notices of objection before July 1st, with J. H. and J. Y. Johnson (47 Lincoln's Inn Fields, W.C.).

### Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** E. D. PAGE [Metal trough casing with plain or transversely corrugated flexible metal lids] 2,461/01; T. MARRIOTT [Bitumen substitute] 3,063/07.

**Dynamos:** G. SAUTTER, E. HARLÉ and J. REY [Compounding alternators with a reaction exciter] 1,430/05.

**Ignition:** A. F. WHITE [Window to observe sparking] 2,853/06.

**Incandescent Lamps:** J. HOWARD [Multiple filament] 2,707/08.

**Storage Batteries:** VAN RADEN & Co. and M. METZ [Construction] 2,727/08; [Fixing electrodes] 25,264/08.

**Switchgear, Fuses and Fittings:** A. H. ADAMS and J. T. MOULD [Motor controllers with interlocked main and rheostat switches] 2,984/02.

**Traction:** SIEMENS BROS. and L. M. G. FERREIRA [Electromagnetic semaphores] 2,961/03; [Detectors for railway points] 3,082/07; J. A. LYCETT and G. J. CONARY [Bogie tramcar truck construction] 3,096/06; G. LOWTHIAN [Locomotive cab signalling] 2,975/07.

**Miscellaneous:** J. FIDDES and J. F. WATT [Fire alarms with sprinklers] 2,772A/04; F. W. HURD [Radial drill] 2,740/08.

# Everybody's doing it

## Trying to keep cool,

and a difficult job, too, in the hot and dusty cities and towns of Great Britain, unless aided by artificial means.

NOW is the time to push

## "FREEZOR" FANS

Now—when the Butcher, the Dairyman, the Fishmonger, &c., cannot keep the flies away—when Restaurants are empty because patrons cannot stand the heat and stuffiness—when the tired and jaded worker lacks energy owing to the heat—when the hotel keeper is expected to provide cool corners for his guests.

*A timely appeal to the right classes at this season will be productive of lucrative results.*

We are engaged upon an extensive campaign for the sale of "FREEZOR" Fans. We are appealing to all classes of electricity consumers, and we know that results will accrue.

Thousands of "Freezor" Fans will be sold this summer—how many by you!!

Let us help you to advertise "Freezor's" in your own district. Let us associate your establishment with this most popular fan. Let us send a representative to discuss this proposition with you.

## LOCAL NOTES

**Blackpool: Street Lighting.**—A saving of £550 per annum in the cost of the street lighting is foreshadowed in the Borough Electrical Engineer's estimates to the Street Lighting Committee. This will be brought about by a reduction in the charges for current for street lighting purposes from 3d. for the first 250,000 units with a sliding scale to a flat rate of 2½d. per unit.

**Burton-on-Trent: Electricity Accounts.**—After meeting interest on capital charges there is a surplus of £1,189 on the electricity undertaking of last year, of which £1,000 is to be applied to relief of rates and the balance carried to renewals fund. This surplus is £1,530 less than in the previous year, due to the increased price of coal.

A new turbo-generator was started up at the electricity works last week.

**Canada: Sale of Electric Lighting Co.**—With reference to the recent notes in our columns concerning a proposal of the Toronto Government to purchase the Toronto Tramway and Lighting Cos., it is now stated that the Toronto Electric Lighting Co. has offered its undertaking at £5,000,000. The valuation of the Company's plant on behalf of the Government is to be put in hand.

**Cromer: Transfer of Electricity Undertaking.**—The agreement for the transfer of the Council's electricity undertaking to Edmundson's Electricity Corporation is now before the Board of Trade.

**Egypt: Water-Power Development.**—The Board of Trade Journal states that the Egyptian Government is considering the development on a large scale of the power at present running to waste through the Assuan Dam. It is believed that the Government will probably set up a small installation in the first instance for the manufacture of calcium cyanamide, which is said to be rapidly coming into favour with farmers as a chemical manure.

**Felixstowe: Tent Lighting.**—An interesting departure has been made by the Suffolk Electricity Supply Co. for the wiring of the tents on the beach and fitting them with a lamp, a kettle, and a radiator for 5s. plus a charge of 10s. for all current used during the period from May 14th to Oct. 14th.

**Galashiels: Electric Supply.**—The Council has decided not to proceed with an electric lighting scheme themselves, but to give facilities for a proposed local company to be formed to take the work in hand. Mr. T. C. Parsons, late Burgh Electrical Engineer at Govan, reported to the Council on the matter.

**Hornsey: Tampering with Fuse Boxes.**—The Electricity Department has had quite a number of cases recently of consumers tampering with their meters and main fuse boxes, and at the last meeting of the Council a warning was given that in all future cases proceedings will be taken.

**Kettering: Electric Supply Accounts.**—The accounts of the electricity undertaking for the year to March 31st show a gross profit of £6,556, and after meeting capital charges and transferring £800 to reserve fund, the net revenue account, including the balance from last year, shows a surplus of £2,069. This result has been achieved notwithstanding coal having cost 40 per cent. more than in the previous year, but this extra cost is being counteracted by the working of the mixed-pressure turbine which is now in operation.

**Oldham: Electricity Accounts.**—There was a net profit of £1,044 on the electricity undertaking last year, which sum is carried forward. There have been large increases in the number of units sold for all purposes, and the generating plant at the Greenhill power station has been increased to 8,600 kw. by the addition of a further turbo-generator set.

**Pembroke (Ireland): Electric Supply.**—An agreement is being entered into for giving the Blackrock Council a supply of electricity in bulk.

**Portsmouth: Power Charges.**—In order to arrive at a general reduction with a view to developing the use of power by small users, a sub-committee has been appointed to obtain information from other supply authorities in this connection.

**Libel Action by Electrical Engineer.**—Mr. George Balfour, who is connected with a large number of important electrical undertakings in different parts of the country, and managing director of Balfour, Beatty & Co., has instituted an action for libel against Ben Tillett, the labour leader. Mr. Balfour was a Unionist candidate at the Govan bye-election, and the statements complained of were in connection with the strike of the employees of the Llanelli Light & Tramways Co.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

## Generating Stations, Sub-Stations, Mains, &amp;c.

**Bootle.**—A Local Government Board inquiry has been held concerning a loan of £3,750 for electrical extensions.

**Canada.**—The Board of Trade Intelligence Department has the name of a coal, railway and power company which contemplates extensions to its power plant, and the electrification of its colliery plant.

**Darwen.**—A Local Government Board inquiry has been held concerning a loan of £6,400 for new plant at the electricity works.

**Leicester.**—A 5,000-kw. generating set with rotary converters, switchgear and boiler plant are to be installed at an estimated cost of £32,350, together with new cables at an estimated cost of £20,000.

**Limerick.**—A loan of £6,100 for the provision of Diesel engine plant is to be applied for.

**London: Hammersmith.**—Estimates have been presented on contemplated mains extensions at a cost of £3,055, in addition to an estimated expenditure of £2,500 on new services, and £2,590 on transformers, sub-stations, &c.

**Norwich.**—The Electricity Committee contemplate an expenditure of £25,000 upon the electricity undertaking during the next five years. A 3,000-kw. turbo-alternator and condensing plant, rotaries, switchboard, &c., are to be installed immediately.

**Oldham.**—E.H.T. switchboard. Borough Electrical Engineer, May 31st.

**Rawtenstall.**—One 1,500-kw. turbo-alternator and condenser. Borough Electrical Engineer, June 10th.

**York.**—An inquiry was held on Monday concerning a loan of £24,440 for extensions at the electricity works. This amount is made up as follows:—Generating plant, £10,100; two water-tube boilers, £4,300; cables, £5,250; battery, £3,900; buildings, £890.

## Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

**Aberdare.**—Cinematograph theatre. C. L. Stewart, Milbourne Chambers, Merthyr Tydfil.

**Bognor.**—New school.

**Cromer.**—Cinematograph theatre.

**Dublin.**—Alterations and additions to the Royal Hospital. Donnybrook. Architects, Beckett & Medcalf, 6 Clare Street.

**Exeter.**—Swimming baths.

**Gillingham.**—New secondary school.

**Haslingden.**—New school.

**London: Bermondsey.**—New baths.

Telephone and bell system at the Western Fever Hospital. Metropolitan Asylums Board, June 4th.

Additions to North-Western Fever Hospital, Hampstead. Metropolitan Asylums Board.

**Maidstone.**—New offices for Prudential Insurance Co.

**Manchester.**—Grange Street Municipal School. Education Offices, Deansgate.

**Margate.**—Public baths and workmen's dwellings.

**Shipley.**—Additions to Otley Road Council School.

**Stirling.**—New municipal buildings.

**Swansea.**—Electric lighting and bells at new training college. Clerk, Education Offices, 9 Grove Place.

**Wakefield.**—Cinematograph theatre. A Winstanley, 5 Blackfriars Street, Manchester.

**West Ham.**—Extensions at Technical Institute, Romford Road.

## Miscellaneous

**Azores.**—The St. Michael's Government has decided to construct an electric tramway system to afford communication with the points of popular interest in the island. The first

line will be to the Valley of Furnas, which is estimated to cost £250,000.

**Belfast.**—The Harbour Commissioners have decided to erect four electrically-driven gantry cranes at an estimated cost of £17,000.

**Bristol.**—The Corporation has decided to convert a further 1,157 street gas lamps to electricity.

**Devonport.**—Twelve months' supply of cables, wires, meters, &c. Borough Electrical Engineer, June 2nd.

**London: Hammersmith.**—A number of 100-kw. and 50-kw. transformers are required by the Council.

**Servia.**—The Servian Telephone Co. requires large quantities of telephone apparatus and material. Direction des Téléphones Serbe, Belgrade. Local representation is necessary, and the name of an agent in Belgrade who is willing to act for British manufacturers may be obtained at 73 Basinghall Street, E.C.

## TENDERS RECEIVED AND ACCEPTED

**Argentina.**—A contract for the supply of 12,000 "Wotan" lamps has been placed with Siemens Bros. Dynamo Works, Ltd., by the Buenos Aires Great Southern Railway.

**Carlisle.**—The following tenders have been accepted:—Generating set, Browett, Lindley & Co., for £2,708; water-tube boiler, superheater, mechanical stokers, &c., Stirling Boiler Co., £1,610; ejector condenser, Korting Bros., £85.

**Harrogate.**—The tender of Messrs. Ferranti, Ltd., at £195 10s. has been accepted for a switchboard extension.

**South Africa.**—A contract for the supply of 3,500 "Wotan" drawn tungsten wire lamps has been placed with Siemens Bros. Dynamo Works, Ltd., by the Union of South Africa.

**Walsall.**—The tender of Callender's Cable & Construction Co. for a main in Darlaston Street has been accepted at £601; that of the British Westinghouse Co. for sub-station equipment at £167 10s.; and that of E. Green & Son for a new economiser at £623.

**Wolverhampton.**—The following tenders have been accepted: British Westinghouse Co., four converters, £2,950; Electric Construction Co., two sub-station switchboards, £408 10s. and £209 10s. respectively; Reyrolle and Co., E.H.T. switchgear for Commercial Road station, £2,000 10s.

## APPOINTMENTS AND PERSONAL NOTES

Mr. Cyril Clarke has been appointed Manager of the Birkenhead Tramways in succession to Mr. W. Wyld, recently appointed Electrical Engineer to the Hampstead Borough Council. Mr. Clarke has been Chief Assistant Manager at Birkenhead for 12½ years.

Mr. A. J. Ryan, Assistant Resident Engineer at the Gillingham electricity works, has received a presentation from the staff on his leaving to take up the post of Chief Assistant Electrical Engineer at Hastings.

The salary of Mr. A. R. Tudman, Borough Electrical Engineer to the Colwyn Bay Council, has been increased from £230 to £255 per annum.

The Coventry Electric Lighting Committee recommend that the salary of Mr. G. Tough, the Borough Electrical Engineer, be increased from £550 to £650 per annum.

The salary of Mr. H. M. Taylor, Borough Electrical Engineer at Middlesbrough, has been increased by £25, making it £450 per annum. Mr. R. H. Scotson, the outside distributing engineer, has had his salary increased from £180 to £200.

The Bristol Corporation Electricity Department requires a sub-station shift engineer with experience of E.H.T. sub-station work. (See advertisement on another page.)

The Birmingham Corporation Electric Supply Department requires a commercial assistant. June 6th. (See advertisement on another page.)

Assistant engineers are required in the Engineer-in-Chief's Department of the G.P.O. (See advertisement on another page.)

**The Strike of Leicester Wiremen.**—As a result of a conference between the electrical contractors of Leicester and their employees, the strike which recently took place has been ended by an agreement to pay 9d. per hour to all wiremen who have worked at the trade not less than six years, with 8½d. to other qualified men of less experience. The new arrangement comes into force as from August 31st.

## MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. G. Smith and Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £72 5s. to £72 15s. (Last week, £72 10s. to £73.)

**Bankruptcies.**—J. G. Hilton, Electrical Engineer, 103 Exchange Buildings, Birmingham, has been adjudicated bankrupt. The first meeting of creditors will be held on June 4th at 10.30 a.m. at 191 Corporation Street, and the public examination is on June 25th at 2.30 p.m. at the Court House, Corporation Street.

**Liquidations.**—A receiver and manager of the X.L. Electric Co. has been appointed, with power to act until October 20th.

The Gem Dynamo Brush Co., Ltd., is to be wound up voluntarily. The liquidator is Mr. J. W. Massey, and a meeting of creditors will be held at his offices, 45 Cherry Street, Birmingham, on June 2nd, at 2 p.m.

**Theft of Electric Fittings.**—A labourer in the employ of the Southwark Borough Council has been sent to prison for six weeks for stealing a quantity of electric fittings, the property of the Electricity Department.

**Curious Accident to a 'Bus.**—Whilst an electric lamp standard was being hauled into position by a tripod derrick in Ludgate Circus on Tuesday, the derrick collapsed and fell on to a passing motor-bus. Fortunately there were no passengers on top of the vehicle at the time.

**The "Point-Fives."**—The June meeting will be held on Tuesday, June 17th, at 7 p.m., at the Delico Restaurant, Barrett Street, Oxford Street, W. The tickets for the dinner are 3s. 6d. each, and may be obtained from the hon. secretary, Mr. A. H. Seabrook. The chairman will address the meeting at about 8.30, and this will be followed by a general discussion dealing with the extension of the use of electricity for domestic purposes, tariffs, apparatus, selling methods, &c. Mr. H. F. Friederichs, Borough Electrical Engineer, West Hartlepool, and Mr. F. W. Purse, late of Watford, and now at Carlisle, have been appointed members of the "Point-Fives."

**The Strength of Metal Filament Lamps.**—The British Thomson-Houston Co. tell us of several examples of the many severe tests to which the strength of Mazda drawn-wire lamps has been subjected. Amongst the accidental tests was, it will be remembered, a shipwreck, in which several cases of Mazda lamps had only suffered damage to the extent of about 1 per cent.—and things are not handled gently during salvage operations. In another instance a stage-lighting batten, containing 100 Mazda lamps, fell five feet, and not one of the lamps was damaged. These lamps had all been burning for some time. The latest, and perhaps most crucial test of all, has just been reported. A 60-watt, 230-volt Mazda lamp, installed at the Palace Theatre, West Hartlepool, fell from a height of twelve feet on to a stone pavement. Although a gallery and heavy bead shade were attached to, and fell with, the lamp, it was found to be in perfect condition when placed in the holder again.

**The Secret of the Permanent Magnet.**—An interesting discourse with this title was given last Friday evening by Professor Silvanus P. Thompson. After demonstrating experimentally the different retentive power of soft iron, soft steel, and hard steel, and illustrating the theory that magnetisation is essentially a change of orientation of the components of material by experimental evidences of the sound, and change of length produced, and the comparative transparency of magnetic "mud," he proceeded to explain the significance of the intercepts of the Ewing cyclic magnetisation curve as measures of the amount of remanent magnetism and its fixidity, comparing the properties of many qualities of steel in these respects. He explained the construction of Ascoli for taking into account the self-demagnetising coefficient by shearing the co-ordinates through a certain angle, and showed how different qualities of steel gave best results for different dimension ratios. A modification of the diagram was also used to explain the sub-permanent nature of a portion of the magnetism. For a treatment of this subject reference may be made to Professor Thompson's lecture last year at Glasgow. The lecturer dealt briefly with the recalcence points of steel, and showed a few micro-photographs of its internal structure. Finally, he summed up the requirements of a good permanent magnet as:—suitable alloy-steel, a shape giving a low coefficient of self-demagnetisation, forging at a moderate temperature, hardening by quenching from a temperature well above the recalcence points, maturing by prolonged subsequent gentle heating to get rid of the subpermanent magnetism. The lecture concluded with a demonstration of the Poulsen Telegraphone.

## SUMMARY

ARRANGEMENTS for interconnecting the mains of the Bury Corporation with those of the Lancashire Electric Power Co., in the event of an emergency, are under consideration. (Page 314.)

At the Mining Exhibition now being held at the Agricultural Hall, all kinds of electric coal-cutters are represented. Miner's electric safety lamps are also in evidence, while the aid of electricity is sought on almost every stand. (Page 315.)

A NEW form of electrically driven two-high rolling mill was described in a Paper by Mr. A. Lamberton at the May meeting of the Iron and Steel Institute. In this, instead of reversing the motor, the return pass is obtained by mechanically interchanging the positions of the rolls. (Page 316.)

THE Gray-Sussmann, Oldham, and Ceag electric safety lamps have been approved by the Home Office for use in mines. (Page 317.)

AN electric mine hoist in Canada is described on page 318.

SPECIFICATIONS published by the Patent Office during May of interest to electrical mining and metallurgical engineers include three dealing with electric furnaces, two for tilting and one for an arc furnace with metal electrodes and a special hearth for the production of alloys. Other patents embrace miner's safety lamps and blasting cartridges. (Page 318.)

A TRIAL run from Dumfries to London is about to be made by an electric car equipped with the Edison battery. (Page 320.)

A CEILING fan, in which special precautions are taken in the design of the bearings and lubrication system, is illustrated on page 320.

At the annual meeting of the Institution of Electrical Engineers last Thursday, Mr. R. A. Chattock, who was proposed independently of the Council nominations, was elected to a seat on the Council. (Page 321.)

SOME details are published from the reports of the Consulting Engineer, Borough Electrical Engineer, and Electricity Committee on the condition of the Walsall electricity undertaking. (Page 321.)

A NEW large asylum has just been finished at Colchester. Electricity is used for power purposes in the laundry, bakery, &c., as well as for lighting. The generating station can take a load of over 200 kw. (Page 321.)

A COOKING outfit in a private house and a new design of enclosed fuse are described in short articles on page 322.

THE inspection and routine testing of electric mining plant is dealt with in our Questions and Answers columns. (Page 323.)

A NEW design of oil switch is illustrated, and a recent installation of condensing plant is described in short articles. (Page 324.)

WE describe the Siemens' standard Telefunken 0.3-kw. ship wireless set, with which a large number of vessels are now equipped.—Considerable difference of opinion exists among the members of the Marconi Committee regarding the terms of their report. (Page 325.)

THE L.C.C. has abandoned its trolley omnibus schemes in consequence of the decision of the House of Commons last week regarding the Borough Councils veto.—An extension of trailer cars in London is to be applied for.—Opposition of several London Borough Councils is threatened to the Post Office tube railway.—"Self-propelled" tramcars are recommended in Edinburgh.—A tube railway between the Isle of Wight and Hampshire is again projected. (Page 325.)

THE specifications published by the Patent Office on Thursday last included several dealing with wireless telegraphy, one for a remote controlled switch with an oscillating armature, by A. H. F. Perl; one covering a method for the speed control of induction motors with short circuited rotors by the employment of adjustable frequency and pressure, by Siemens Schuckertwerke; and one for a self-regulating dynamo, by Geo. Polkey, Ltd. (Page 326.)

THE West Ham Electricity Department has in use two Edison electric battery vans.—There are now 1,500 looms with individual motors supplied from the Blackburn electricity works.—The Dundee Electricity Department has built up a £21,000 reserve fund in three years.—A sum of £24,500 is to be paid to relief of rates from the Manchester electricity profits for last year. (Page 327.)

ELECTRICAL extensions are contemplated as follows:—Wallasey, £65,000; Worthing, £6,750; Southwark, £29,464; Bispaham, £8,155; York, £6,800; Hebden Bridge, £3,250; Halifax, £23,180.—Air-cooled static transformers are required at Hammersmith; double-deck trolley omnibuses at Brighton; cable at Southampton; and a twelve months' supply of electrical stores by the Penrikyber Navigation Colliery Co.—Electric lighting schemes are under consideration at Dolgelly and Tullamore. (Page 327.)

THE American Westinghouse Co. made a profit of about £600,000 on its past year's trading, and an 8 per cent. dividend is to be paid.—A scheme for the consolidation of the Edison & Swan United Electric Light Co.'s debentures has been formulated. (Page 328.)

**Single-phase Commutator Motors.**—At the Annual General Meeting of the I.E.E. Students' Section, a Paper was read by Mr. E. A. Richards and Mr. D. Dunham, in which they described a series of tests on a 140 volt, 57 ampere, 1,430 r.p.m. Fynn single-phase motor when connected as an Atkinson, Latour-Winter-Eichberg and synchronous machine. It was found that for the Fynn, L.W.E., and synchronous connections, at 6 b.h.p., the efficiencies were nearly the same, although the losses were made up in rather different ways. Friction and windage accounted for approximately 40 per cent. of the losses, and about one-third of this consisted of brush friction. The copper losses in each case were under 30 per cent., whereas the iron losses and circulating currents came to 6 per cent. of the total with the synchronous motor connection, 8 per cent. with the Fynn, and 14 per cent. with the L.W.E. connection. With the Atkinson connection the maximum output was 3 b.h.p., and the efficiency 50 per cent. In this case the friction and windage also accounted for about 40 per cent. of the total, the iron losses and circulating currents 21 per cent., and the copper losses 36 per cent. of the total. A new type of motor, due to Mr. F. Creedy, in which the stator has salient poles and the rotor an ordinary D.C. armature with three brush sets on the commutator, was also described. Compensation is produced by an external transformer with the primary in parallel with the stator. The power factor of the whole motor reaches about 91 per cent. at full load, with an efficiency of about 74 per cent. The motor tested was designed for lift work, and gives a very high starting torque. Starting is effected by switching the motor straight on the mains.

## ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, JUNE 5TH.

*Institution of Mining Engineers.*

- 11 a.m. At Burlington House, Piccadilly. Among the papers to be read (at 2.30) will be "Insulated and Bare Copper and Aluminium Cables for the Transmission of Electrical Energy, with Special Reference to Mining Work," by B. Welbourn.

SATURDAY, JUNE 7TH.

*Association of Mining Electrical Engineers.*

- 5.30 p.m. Warwickshire and S. Staffs. Branch. At Imperial Hotel, Temple Street, Birmingham. "Notes on Colliery Generating Plant," by W. Bolton Shaw.

THURSDAY, JUNE 12TH.

*Tramways and Light Railways Association.*

- 10.30 a.m. Annual Congress at Blackpool. At Imperial Hotel.

FRIDAY, JUNE 13TH.

*Tramways and Light Railways Association.*

- 10 a.m. Annual Congress (continued).

*Physical Society.*

- 8 p.m. At Imperial College of Science. "Some Experiments on Tinfoil Contact with Dielectrics," by G. E. Bairsto.

## The London Electrical Engineers.

(TO-DAY) THURSDAY, JUNE 5TH.—C. Company. FRIDAY, JUNE 6TH.—D. Company. MONDAY, JUNE 9TH.—A. Company. TUESDAY, JUNE 10TH.—B. Company. THURSDAY, JUNE 12TH.—C. Company. FRIDAY, JUNE 13TH.—D. Company. Infantry Drill, 7 to 9 p.m. Technical instruction for all Members on the Sixth Rate and for all Candidates for Higher Rating, 7 to 9 p.m. Musketry Instruction, 9 to 10 p.m.

SATURDAY, JUNE 14TH.—Headquarters open from 10 a.m. till noon.

**"Electrical Combine: Civic Scheme to Meet any Emergency."**—Under this heading a Lancashire paper last week published a statement that an important scheme would be given practical consideration in the very near future for the interconnection of electric mains belonging to local authorities and companies round about Manchester, so as to maintain a supply of current in case of a breakdown. This very much overstates what is really occurring. The true facts of the matter are that the Bury Corporation are considering the question of interconnecting their mains with those of the Lancashire Electric Power Co. The interconnection of other electricity works in the Manchester district in a similar manner of course would be very desirable, but we understand that no definite scheme in this direction has been formulated, at any rate at present.

WAS THE CHIEF PLEASED?

**MAINS FOREMAN**, at telephone (time 4.30 a.m.). That you, sir? We didn't like to bother you before, but I thought you'd like to know that the lights have been out in feeder districts 1 and 2 since half-past ten, and that we have just got current on again.

## ELECTRICAL ENGINEERING IN THE MINING AND METAL INDUSTRIES

### THE MINING EXHIBITION

THE uses of electricity in mining are fairly well represented at the Mining Exhibition, which was opened at the Agricultural Hall on Thursday last, and continues until Saturday next. The larger proportion of the coal-cutters exhibited are electrically driven, electric safety lamps also make a good show, and other miscellaneous uses of electricity are everywhere in evidence. Electrically-driven coal-cutters are best represented on the large stand of Mavor & Coulson, Ltd. (Glasgow), where the compact machines for D.C. and A.C. working, which have for a great many years been made by this firm, are on view. To demonstrate the smoothness with which the speed-reducing gears work, one of the machines is arranged with a small handle on the motor end. The motors are cooled by an air current in a novel way. The motors are gas tight, with gauze-protected openings at each end, while on the shaft in a separate chamber from the rotor is a fan, which draws air in through one of the gauze openings and forces it through a number of small tubes, passing close to the outside of the stator stampings to the opposite end, where it is discharged into the air through the other gauze openings. The heat produced by the motor is thus carried away, first by convection to the tubes and thence by conduction to the air stream, whereby no dangerous gas or dust can be brought in contact with the interior of the motor. As is known, this company does not build many "chain" machines, but has introduced and developed the "bar-pick-quick" type, which is now made with a fast-cutting double worm. "Disc" machines are also largely made, but, owing to the liability of the cutting wheel to get jammed if certain obstructions are met with, the rotors of induction motors for driving these machines must be of the wound type, while for the bar-pick-quick machines a squirrel-cage motor is used, on which the end rings are cast solid. A new feature is a design of aluminium, micanite insulated, pommel for use with the coal-cutters and other machines. It is made in two halves, and is very convenient to wire, and is fibre-protected where necessary. This company have also a display of gate-end switch-boxes, dust-extractors, and other machinery. Other firms exhibiting coal-cutters include the Diamond Coal-Cutter Co., Ltd. (Wakefield), who make a good show of junction-boxes, gate-end cable winches, and disc and chain coal-cutters, as well as their recently introduced bar machines. The Sullivan Machinery Co. (Salisbury House, E.C.) show chain machines developed at their works in the United States. These they claim are suitable for any kind of service, and machines are now being worked for extremely hard holing, such as in anthracite, in clay pavement, and in bituminous coal containing many hard impurities. Some of the features of these machines are that the feed may be reversed without stopping the motor, resetting the jacks, or moving the feed chain; while interposed between the armature pinion and the sprocket which drives the feed chain is a friction clutch, which is adjusted so as to slip before any excessive stress can come on any part of the machine. Besides ordinary "long-wall" machines, the company also has a continuous cutter on the long wall principle for undermining coal in headings and stalls, to which a pioneering claim is made. Anderson, Boyes & Co., Ltd. (Motherwell) are exhibiting on their stand both disc and chain machines, as well as an electric header and some switchgear, including gate-end and trifurcating boxes of substantial design. "Crescent" disc coal-cutters are shown on the stand of A. Hirst & Son, Ltd. (Dewsbury). These may be obtained specially low if necessary.

Besides the exhibitions of switchgear already mentioned, the Electrical Apparatus Co., Ltd. (Vauxhall) have on view both direct- and alternating-current gear. The former is represented by a panel comprising several units, all totally enclosed. A motor-starter is fitted with a slow-motion device which allows a rapid motion from step to step, but ensures a definite stop on the centre of each. A solenoid-operated starter for the automatic or remote control of machinery is also shown. A feature of this is that the main switch and resistance-controlling levers are operated by separate iron cores, moving one at each end of a single solenoid coil. Among the alternating-current gear may be mentioned a

triple-pole oil-switch with oil level interlock, by which the switch cannot be closed unless there is sufficient oil to cover the contacts. Various samples of parts and materials are also exhibited. Electrically-driven pumps are represented on the stand of Gwynnes, Ltd. (Hammersmith), where there are one or two centrifugal pumps constructed to the order of the New South Wales P.W.D.: 75,000 gallons of water can be delivered per hour against a head of 517 ft. A special pump is also shown, in which any solids which enter the suction pipe can pass through the pump. Submersible motors, made by Submersible & J.L. Motors, Ltd. (Southall), are used for all the pumps. These motors can be used in fiery mines, as they can be totally immersed in a tank of water. Another branch of heavy electrical equipment is supplied by the Union Cable Co., Ltd. (Dagenham Dock), who have a range of samples showing all classes of insulated cables for power, light, traction, and telephony, as well as a display of bitumen-insulated mining cables and joint-boxes.

Among the electric safety lamps shown are those on the imposing stand of the "Ceag" Electric Safety Lamp Co., Ltd. (London), where a multitude of "Ceag" lamps are displayed. These and the other lamps awarded prizes in the Home Office competition have been already fully described in ELECTRICAL ENGINEERING, and are now well known. Charging sets, lamp racks, magneto-openers, &c., are also on view at this stand, as well as at the stand of the Cremer Lamp & Engineering Co., Ltd. (Leeds), who also make a cylindrical miner's lamp of very robust construction, as evidenced by the rough usage to which the lamps are put for demonstration purposes. Inspection lamps in aluminium cases and one in a sheet metal case, with a number of lamps on a movable steel tube, so arranged that the light can be regulated in strength and direction, are also included. Acroyd & Best, Ltd. (Morley) also show some lamps made under Hailwood's Patents, as well as their well-known relighting machine for oil lamps, while John Davis & Son (Derby), Ltd. (Derby), have an exhibition of Gray-Sussman lamps, which are made in several sizes. Special attention has been given to the battery, which does not show any tendency to leak when held upside down, and to the magnetic lock. This is of substantial construction, and can only be opened by the special magnetic opener provided. It would be most difficult to open it any other way. This firm also have on view a large variety of accessories for different purposes, including Berry interlocked switchgear with illuminated indicators, compact shot-firers, and the Davis-Fryar mechano-electric signals for haulage planes, &c., in gassy mines. These are designed to comply with Rule 15 in the Home Office Special Rules for Electricity in Mines. Instead of fixing a series of gas-proof press buttons at frequent intervals so as to avoid open sparking, a contact maker of special design is erected about every 200 yards, and in either direction from this flexible pull wires are run over guide pulleys at 5-yard intervals along the sides of the road. The patent covering this system was abstracted in ELECTRICAL ENGINEERING, December 5th, 1912. This firm, as well as Siebe, Gorman & Co., Ltd. (Westminster) show Professor J. S. Haldane's new design of catalytic detector, while Manley & Sandey, Ltd. (King's Cross), are showing their catalytic detector, which is made of an alloy with no temperature coefficient, as well as neat lamp cabin equipment.

A very imposing stand is that of Bleichert's Aerial Transporters, Ltd. (Egypt House, 36 New Broad Street, E.C.). Here there is a working model of an aerial wire ropeway and relief models, in gypsum, of the large ropeway built for the Famatina Mines in the Argentine, and of the remarkable wire ropeway built for Wilkins & Wiese in East Africa. This line is about 5½ miles long and has a rise of 5,000 ft., equivalent to a gradient of 41 degrees or 86 per cent. Besides a full size 4-wheel carriage there is a full size working model of an automatic telfer. These lines are fitted with remote control, as are, of course, those driven electrically. A natural size telfer car, as used in mines and iron works, is also working. The motive power is supplied by enclosed electric motors, and a patent block system is provided, so that collision on the track, at crossings or switches, are impossible. The cars can be provided with winches for lowering and hoisting, or with automatic grabs for handling ores, coal rubbish, &c. These

automatic cars have been constructed for effective loads up to 2½ tons.

Electricity is also the agent for transmitting power to the fans, blowers, portable forge, &c., exhibited by Jas. Keith & Blackman, Ltd. (Farringdon Avenue), and for the many "Sirroco" centrifugal fans shown by Davidson & Co., Ltd. (Belfast), on their interesting stand, where there is a model arrangement for reversing the air current without touching the motor; while the Mining Appliances Co. (Sheffield) have a working exhibit of a through conveyor and other appliances. Neither can one leave the subject of the exhibition without a word about the Kennicott Water-Softener Co. (Wolverhampton), who show one of their latest type "K" small plants for 1,250 gallons capacity—plants up to 30,000 gallons per hour have been made. The apparatus depends on the action of lime and soda, and is so arranged that it is continuous and wholly automatic in its action. If the water to be treated has "temporary" hardness only, no lime is required, and the revolving sludge pipes prevent accumulation of sludge, so that the tank never requires opening for cleaning. On this stand there is also a tray-type boiler feed-water heater for the utilisation of exhaust steam. Directly associated with the use of electricity is the epicyclic speed-reducing gear shown by Joseph Baker & Sons, Ltd. (Willesden Junction). These gear wheels have a large number of accurately cut teeth, so that the driving force is equally distributed. Several speeds forward and a reverse may also be easily provided for. A self-adjusting earthing and continuity clip which fits any size cable, conduit, or pipe, is shown by Hann & Ingle (Manchester), and an interesting exhibit of the pulmotor automatic oxygen-reviving apparatus is shown by Richard Jacobson (Shoe Lane, E.C.).

### A NEW FORM OF ELECTRICALLY DRIVEN ROLLING MILL

ONE of the Papers read at the May meeting of the Iron and Steel Institute in London was on "A New Form of Electrically-driven Two-high Continuous-running Reversing

the cost of current was low enough. For light sections the three-high continuous-running mill was practically universal, and in such cases the electric motor left nothing to be desired. For larger sections, however, there was the objection that complicated live roller tables were required to rise and fall at each pass, and there were difficulties in the exact setting of the rolls. These considerations had caused many steel-makers in the country to prefer the two-high reversing mill, even though its driving was less economical.

This being so, it occurred to the author that if two-high section rolling mills could be designed so as to be capable of being driven by a continuous-running electric motor, and at the same time give the necessary reversals to the bar at each pass, this would go a long way to meet the difficulties. The root idea of his new system by which this is accomplished is that, if in a mill with two rolls arrangements can be made to make the bottom roll the top roll, and vice versa, then at each reversal of the position of these rolls there will be a pass in the opposite direction. Referring to the figure, the two rolls, A, are mounted in the usual form of chocks, B, contained in the circular gables, C, which gables are free to rotate in the fixed frames or housings, D. In order to make the turning of the gables easy, these are carried on broad revolving anti-friction rollers, E, placed immediately under the gables, and carrying their weight. These anti-friction rollers have part of their breadth formed into a spur pinion, F, which gears with corresponding teeth in the rotating gables. By means of a hydraulically-operated rack, G, gearing into a pinion on the bottom roller shaft, H, the rotation of the gables is quickly effected, the time taken being only three to five seconds, and the stroke of the hydraulic rams is just sufficient to bring the rolls to their exact position at each reversal. To provide for the alternative change in the position of the top and bottom roll, the driving spindles, J, conveying the power from the mill pinions, K, to the rolls, A, are disposed in the manner shown on the drawing, and the weight of these spindles is borne up in their centre by a balanced carrying gear, the weight of the descending spindle balancing that of the ascending spindle

PLAN AND ELEVATIONS SHOWING GENERAL ARRANGEMENT.

Mill," by Mr. A. Lamberton. The author was not fully convinced of the advantage of electrical driving over other methods for large reversing mills, but said that all engineers were in agreement that where rolling mills could be driven by a constant-running motor associated with a heavy fly-wheel, electrical driving was to be preferred, provided that

at each reversal. The mill pinions are placed side by side, and not superposed as is usual, as this reduces the angle on the spindles during reversals. The first mill of this new type is now in course of construction, and will be put to work in a large steelworks in England in the early summer.

During the discussion, the opinion was expressed that from

3 to 5 seconds was rather a long time for reversal of a mill. Some points in the mechanical design of the proposed mill were also criticised. Another speaker was distrustful of a flywheel in conjunction with a continuously-running motor, but Mr. Lamberton, in his reply, pointed out that there was no danger because there was the braking spindle between the flywheel and the mill. He had always thought that a continuous running motor, coupled to a flywheel, was the finest drive for a rolling mill.

### ELECTRIC MINERS' LAMPS

THE Gray-Sussmann (Nos. 3 and 4), the Oldham, and the "Ceag" miners' electric safety lamps have been approved by the Home Office for use in mines.

According to the official description, the Gray-Sussmann lamp, which is illustrated in Fig. 1, possesses the following essential parts:—(1) A sheet-steel case with securely soldered joints, tinned or galvanised, and enamelled on the inside. (2) An electrical accumulator, so constructed as to prevent escape of the liquid whatever the position of the lamp, whilst allowing the escape of gas generated by chemical action in

FIG. 1.—GRAY-SUSSMANN LAMP.

the accumulator. (3) A hinged stamped-steel cover, tinned or galvanised, forming a flame-tight connection with the case, and secured thereto by (4) an efficient locking device of one or other of the following types:—(a) A lead rivet lock; (b) a magnetic lock, so constructed that the bolt can only be withdrawn by applying the pole of an electro-magnet to the face of the lock. (5) An insulated domed base plate of aluminium or brass, secured to the cover of the case by means of a screw, and carrying the bulb, switch, and two spring contacts making connection with the terminal lugs of the accumulator. (6) A flame-tight screw-switch in the base plate. (7) A top-plate of aluminium or brass, carried by four brass pillars screwed to the top plate, and secured to the cover of the case by nuts on the inside and outside of the cover. (8) A stout protecting glass held in position by the top-plate and pillars, and forming flame-tight connections between the top- and base-plates by washers of indiarubber or asbestos.

The lamp is approved for use under the following conditions:—Provided—(1) That the lamp may be made in two sizes, one of which shall be named the Gray-Sussmann Electric Safety Lamp No. 3, and the other the Gray-Sussmann Electric Safety Lamp No. 4. (2) That the total weight of the lamp is not more than  $5\frac{1}{2}$  lbs. in the case of No. 3, and 6 lbs. in the case of No. 4. (3) That the strength of material and attachments throughout the lamp is not less than in the sample submitted to tests on the 4th March, 1913. (4) That the lamp shall be capable of maintaining a light of not less than 1 candle-power all round in a horizontal plane throughout a period of not less than 9 hours, and also of giving a light of not less than 1.5 candle-power over an arc of 45 degrees in a horizontal plane. (5) That the lamp has been made at the works of Mr. W. E. Gray at 19 Archer Street, Camden Town, London. (6) That the lamp shall have marked upon it its name and the name of the maker.

The Oldham lamp is illustrated in Fig. 2, and according to the official description, possesses the following essential parts:—(1) A solid drawn steel case (tinned). (2) An electrical accumulator, the terminals of which are fitted with spiral springs carrying rubbing contacts: the construction of the

accumulator being such as to prevent escape of the liquid, whatever the position of the lamp, whilst allowing the escape of gas generated by chemical action. (3) A top screw plug carrying the bulb, protecting glass, pillars and crown, and forming a flame-tight connection with the case: the protecting glass, pillars and crown, being of any of the types shown in the plate. (4) A bottom screw plug carrying the accumulator

FIG. 2.—OLDHAM LAMP.

and forming a flame-tight connection with the case. (5) An efficient locking device of one or other of the following types, to prevent unauthorised persons from unscrewing the bottom plug, viz.—(a) A brass locking bolt, held in position by a lead rivet; (b) a magnetic lock, so constructed that the locking bolt can only be withdrawn by applying the pole of an electro-magnet against the cover of the lock.

It is approved for use:—Provided—(1) That the total weight of the lamp is not more than 5 lbs. 4 ozs. (2) That the strength of material and attachments throughout the lamp is not less than in the sample submitted to test on the 7th and 8th January, 1913. (3) That the lamp shall be capable of maintaining a light of not less than 1 candle-power all round in a horizontal plane throughout a period of not less than 9 hours, and also of giving a light of not less than 1.5 candle-power over an arc of 45 degrees in a horizontal plane. (4) That the lamp has been made at the works of Messrs. Oldham and Son, at Denton, near Manchester. (5) That the lamp shall have marked upon it its name and the name of the maker.

The "Ceag" lamp, which obtained the first prize in recent Home Office competition, is illustrated in Fig. 3. According to the official description it possesses the following essential features:—(1) A solid drawn-steel case (tinned), strengthened by pressed corrugations; fitted with securely attached steel lugs, or brass screw ring, for the attachment of the cover. (2) An electrical accumulator, the terminals of which are fitted with spiral springs carrying rubbing electrical contacts; the construction of the accumulator being such as to prevent escape of the liquid, whatever the position of the lamp, whilst allowing the escape of gas generated by chemical action. (3) A cover, carrying the pillars and crown, either (i) of stamped steel (tinned), fitted on the inside with a securely attached stamped steel ring provided with feathers to engage lugs on the case; or (ii) of brass, screw threaded internally to engage the screw ring on the case. Provided that the cover, whether attached by bayonet joint or screw, shall form a flame-tight connection with the case. (4) A metal plug, with insulated connections screwed to the inside of the cover, and carrying the bulb and a spiral spring, which is kept in compression when the bulb is in position. (5) A stout protecting glass secured to the cover by the metal plug described in paragraph (4) and forming a flame-tight connection with the cover by means of asbestos or india-rubber washers. A steel spiral

spring, kept in compression between the protecting glass and the bulb, holds the latter in position. (6) An efficient magnetic lock, securing the cover to the case, and so con-

FIG. 3.—"CRAG" LAMP.

structed that the bolt can only be withdrawn by applying the pole of an electro-magnet to the outside of the lock.

The following are the conditions under which it is approved for use:—Provided (1) that the total weight of the lamp is not more than  $5\frac{1}{2}$  lb. (2) That the strength of material and attachments throughout the lamp is not less than in the sample submitted to test on the 16th March, 1913. (3) That the lamp shall be capable of maintaining a light not less than 1 candle-power all round in a horizontal plane throughout a period of not less than nine hours, and also of giving a light of not less than 1.5 candle-power over an arc of  $45^\circ$  in a horizontal plane. (4) That the lamp has been made at the Corcordia Works of the "Ceag" Electric Safety Lamp Co., in Dortmund, Germany. (5) That the lamp shall have marked upon it its name and the name of the maker.

### AN ELECTRICAL MINE HOIST IN CANADA

THE conditions in Northern Ontario have always been very favourable to the introduction of electrical driving for all mining purposes on account of the scarcity of fuel and the abundant water supplies available. The mine of the Mond Nickel Company, from which a rich nickel ore is produced from approximately 1,000 ft. depth, has been working for over ten years with electric drive. The Company has its own power-station, whence three-phase power is transmitted over a distance of four miles at high pressure to a sub-station, where the pressure is reduced 550 volts. All the motors for pumping, hauling, ventilating, winding, &c., work at this pressure. The mine hoist is driven by a 300 h.p. slip-ring motor controlled by a series relay type, reversible controller, which is in turn controlled by a master drum. The controller consists of two double pole contactor switches with blow-outs for the control and reversal of the primary circuit, and a number of similar D.P. switches for the control of resistance in the rotor. These switches are in turn controlled by 3-phase series relays connected in the rotor circuit so that they prevent the closing of the accelerating switches until the motor has come up to a certain speed and the

accelerating current has dropped to a predetermined value. The master drum is of the multi-step type, by means of which the operator is enabled to start and reverse the motor and run it at any speed desired. Should he throw the master drum quickly to the full-speed position, the motor resistance would not be cut out suddenly, but the acceleration is controlled by the series relays. The hoist is stopped by means of hand brakes, and is equipped with an emergency brake, which is set by a falling weight, this weight being held suspended by a latch. On failure of the line current, this latch is tripped by an A.C. solenoid, and after the current is re-established the brake is re-set by hand.

### ELECTRIC MINING AND METALLURGICAL PATENTS OF MAY

#### Mining.

The Specifications which were published by the Patent Office during May, having particular interest for mining electrical engineers, include No. 5,073/13 by H. F. Joel (Forest Gate). This covers a simplified mechanical construction of the casing and switch in the type of miners' safety lamp developed by the inventor. The lantern and battery casing are connected by inclined slots and set screws, so arranged that when the screws abut against the ends of the slots, the switch rod and lamp and battery terminals are in their working position where they are locked. The switch rod, which passes through a hole in the battery cover, ensures that the enclosure cannot be opened until it is withdrawn to the off position. Specification No. 20,445/12 by J. Lamour (Germany) deals with blasting in fiery mines, and embraces transmitting the force of the explosion through water in a vessel in the borehole. There is no substantial ejection of water until the rock or coal has been shattered, so that time is given for the products of the explosion to be cooled. Another Specification dealing with blasting is No. 16,536/12 by N. Field (Newcastle-on-Tyne). The detonator tube is located on one side of the glass cartridge case, to which it is inclined. The two are made in one piece. The object is to protect the explosive from moisture, and to prevent perforation of the cartridge case.

#### Metallurgical.

The Specifications of interest to electro-metallurgical engineers, published during the month of May, had amongst them No. 26,165/12 by The Jössingford Mfg. Co., A/S. It is sought to combine the advantages of furnace electrodes, mounted on galleys and suspended by chains, by using a travelling electrode-carrier mounted on a trolley, which is locked to the furnace, and may be tilted with it. In No. 26,166/12, the same inventors describe an arrangement whereby, in a tilting furnace, the tilting force acts approximately in a vertical direction during the whole of the tilting operation. The tilting force acts through linkwork, so that tilting is effected along a straight track without the use of toothed gearing. Specification No. 8,791/12, granted to E. C. R. Marks (communicated by the Patents Purchasing Co., U.S.A.), covers the use in arc furnaces for the production of alloys of vanadium and aluminium and other metals, of an adjustable non-metallic hearth forming one electrode, and metallic electrodes of iron or of the metal to be reduced. The material to be treated is passed continuously, in a finely-divided state, through the arc. The hearth, which is supported on a truck, forms a temporary support, and a channel is arranged to carry off the molten material. The other electrodes are supported on trucks running on inclined guideways, and are electro-magnetically controlled.

**Electrical Drive for Underground Conveyors.**—In the course of a Paper read recently before the South Wales Institute of Engineers, Mr. Sam Mavor described the construction and use of a number of types of underground face conveyor, and remarked that where electricity is the motive power the total power cost was moderate. At an energy cost of 1d., he continued, per unit, the cost for eight hours for a conveyor 100 yards long is about 3s. Where compressed air is used the efficiency is much lower, and this is emphasised by the fluctuating character of the load on the air motor, because the amount of compressed air used is more nearly proportional to the time of working than to the load upon the motor. At a cost of 0.65d. per b.h.p. delivered to the compressor (equivalent to 1d. per unit for electricity) the cost of power for eight hours' running is about 10s., without allowing anything for losses in transmission or leakage; providing for these losses the cost is about 12s. for eight hours' running.

## EDISON BATTERY CARS

A GOOD deal of activity is now being shown in the application of the Edison battery to motor-car work in this country, not only in the direction of commercial vehicles, several of which are now to be seen about London both as demonstration vehicles undergoing trials under service conditions, and as in the case of the West Ham electricity department in permanent use, but also in the construction of private passenger cars. We announced recently that Arrol Johnson, Ltd., were putting down a large batch of electric cars propelled by the Edison battery at their works at Paisley, and we are now able to state that one of these cars, in a fully finished condition, with a handsome coupé body, driven from inside, is about to start on a trial run from Dumfries to London, which, if successful, will form an epoch-making achievement. We are not yet in possession of full technical details of the car, but we understand that it has an underhung frame, and is driven by a single motor placed about the centre of the chassis through an undertype worm gear on to the live back axle. The cells are, we believe, stowed partly in the forward bonnet, which is the well-known form adopted in the Arrol-Johnson petrol cars, and partly in the rear of the vehicle, so that the lines of the body are in no way spoilt by the unsightly battery-box, which has been a feature of some previous electric cars. The motor is rated at  $3\frac{1}{2}$  h.p., with overload capacities of 300 per cent. for  $\frac{1}{4}$ -hour and 100 per cent. for one hour. The control is as simple as possible; plain series resistances are used on the first few steps. As there is only one motor with a single commutator, series parallel control cannot be made use of in any way, nor is there any alteration in the grouping of the cells, which are kept permanently in series. The characteristic of the motor, however, enables quite steep hills to be taken on the top controller notch without undue current being taken from the battery. Thus the resistances are only in circuit at starting. The motor has an efficiency not falling below 80 per cent. from full up to its maximum overload, and thus, when developing its rated load of  $3\frac{1}{2}$  h.p., must take about 50 amperes from the 65-volt battery. We regret that at the time of writing we have not full details of the battery capacity, nor the weights of the battery and car before us, but we are told that with extreme care in driving, as much as ninety miles can be run on one charge with a battery of the size in question, or from thirty-five to sixty in ordinary work, according to circumstances. It is not intended in the forthcoming run to attempt records in this direction; attention will rather be concentrated on proving reliability and ability to run to a given time-table.

The car, which, we understand, will carry an independent observer is to start from Dumfries on Monday morning next at 5 a.m., and is expected to arrive at Carlisle at 8, where a stop of one hour will be made for charging and breakfast. Penrith, where a half-hour's charge will be taken, should be reached by 10.30, and the next stop of one hour for charging and lunch is to be made at Kendal, which is timed to be reached at 1.30, and a further short charge will be taken during a half-hour stop from 4 o'clock at Lancaster, where the Mayor and other notabilities have promised to inspect the vehicle. Continuing, Preston will be reached at 6, where an hour is allowed for dinner for the battery and passengers. The first day's run is to conclude at 9.30 at Manchester, a total distance of 159 miles in  $12\frac{1}{2}$  hours' running time. Evidently no attempt will be made to approach the legal limit. The next day's run will be arranged on similar lines, with stops probably at Rugby, Northampton, Bedford, Luton, Hitchin, and Barnet; this rather roundabout route is necessarily chosen to take advantage of charging stations. London is expected to be reached finally at 11 o'clock on Tuesday evening. The trip will be a remarkable one, and should do much to draw attention to the possibilities of the Edison battery, but of course it is not intended to imitate real touring conditions such as can be met with a petrol car of higher power. The true field of the electric car is for urban work, where a low speed and limited radius of action is all that is necessary, and for such its cleanliness, simplicity, ease of control, and, in these days of rising petrol prices and falling electricity tariffs, probably also its cheapness of running give it an excellent chance of popularity now that the Edison battery, with its appreciably lighter weight and greater robustness than the lead battery, is available. Already, as we have indicated above, a good start has been made in commercial work, where the good qualities of the Edison battery show perhaps to the best advantage, and we must congratulate Mr. W. H. L. Watson, of "Edison Accumulators" (41 Great Portland Street), on the progress he has made in the short time during which he has had the matter in hand in this country. Those

unfamiliar with the construction and working of the Edison alkaline nickel-iron battery may be referred to detailed articles which appeared in *ELECTRICAL ENGINEERING*, October 12th, 1911, Exhibition Supplement, page 67, and May 19th, 1910, page 319.

## THE SWAN CEILING FAN

AN ailment common to many ceiling fans is the leakage of lubricant from the upper bearing, not only on to the commutator and armature, but on to the fan blades, where it is reinforced by a further leakage from the lower bearings, and is disseminated about the room. Attempts to overcome this difficulty have taken the form of a lower thrust bearing designed to sustain the whole weight of the fan, and to relieve the upper bearing of the necessity for lubrication. In such an arrangement the slightest error in the centring of the armature in the field magnets sets up such severe strains in the overhung bearing, owing to want of balance in the magnetic pull on the armature, that the bearing is quite unable

SWAN PATENT CEILING FAN, SHOWING DETAILS OF MOTOR.

to withstand them. In the Swan ceiling fan, which is manufactured by the General Electric Co., Ltd. (67 Queen Victoria Street, E.C.), the problem has been met by combining the advantages of an end thrust bearing with those of a lubricated upper bearing. First, a simple bearing has been designed to which no exception can be taken for rigidity and freedom from stresses arising from a de-centring of the armature, and, secondly, the upper bearing is adequately lubricated for the work it is called upon to perform. An idea of its general construction is to be gained from the illustrations. The design frees the fan from all the troubles arising from leaking lubricant, and at the same time gives the fan considerable constructional strength.

**Institution of Electrical Engineers.**—The following is the result of the ballot for new members, and transfers from one class to another, at the annual meeting on Friday:—**Members:** H. Leitner, A. N. Moore. **Associate Members:** G. W. Carpenter, F. J. Culligan, E. I. David, W. da F. Davids, A. Davis, P. A. Fildes, E. W. Fulcher, E. C. Gage, G. F. Gregory, A. R. Hemsted, S. Hill, N. V. Lloyd, N. McLachlan, E. P. Neate, R. O. Neil, S. C. Newton, J. I. Robertson, E. Sidgwick, T. Smith, T. W. Smith, G. E. Swift, A. H. Trench, C. R. Ward. **Associates:** I. Hemmings, G. Phillips, O. Thomson. **Graduates:** A. J. Arthur, J. H. Borland, P. H. Brewer, E. F. Hollands, G. N. Hurst, C. H. Jeffcoat, W. H. King, A. McPherson, M. R. Soi. **Students:** A. E. Beach, R. Dods, L. D. Hill, P. V. Hoare, J. W. Kilby, F. H. Lawrence, P. J. Wood. **CANDIDATES TRANSFERRED:**—**Associate Member to Member:** R. L. Alkin, J. D. Dallas. **Associate to Associate Member:** F. E. Davies, A. B. Newman, C. Turner. **Graduate to Associate Member:** H. G. Furlong. **Student to Associate Member:** R. D. Fairclough, G. Ingram, P. E. Peronne, L. F. Summers, T. H. West, J. M. Whellens. **Student to Graduate:** H. Bond, D. N. Jenkins, F. P. Lacey, H. J. Loughlin, S. K. Srivastava.

## ANNUAL MEETING OF INSTITUTION OF ELECTRICAL ENGINEERS

THE annual meeting of the Institution of Electrical Engineers was held on Friday, May 31st. The first business was the announcement of the result of the ballot for new members of Council, the nominations for which were given in our issues of April 8rd, p. 183, and April 24th, p. 224. Mr. R. A. Chattock, City Electrical Engineer, Birmingham, was elected to the vacancy as an ordinary member of Council; to fill the three vacancies as associate members of Council, Mr. F. E. Berry, Capt. E. O. Henrici, R.E., and Mr. A. W. Martin were elected; and as associates, Mr. E. Russell Clarke and Mr. A. M. J. Ogilvie were elected. The honorary officers were also re-elected.

The annual report of the Council, abstracted on p. 284 of our issue for May 22nd, was then adopted without discussion.

Mr. Robert Hammond, the Hon. Treasurer, in presenting his annual report, said that the revenue from amount received for life compositions had not been treated as revenue for the year, but had been invested. He also drew attention to the fact that the enlarged funds of the Institution had permitted the purchase of some very much needed experimental apparatus. The assets of the Institution, he added, amount to £110,368, against liabilities of £45,150. The accounts were then adopted. Votes of thanks to the honorary officers concluded the proceedings.

## THE WALSALL ELECTRICITY UNDERTAKING

THE full text of the report of Mr. E. M. Lacey on the condition of the Walsall electricity undertaking, together with the comments thereon by Mr. A. S. Barnard (Borough Electrical Engineer), and the report of the Electricity Committee, are now available.

Mr. Lacey attributes the recent troubles to the inability of the boiler-house plant to raise sufficient steam to deal with the load without undue forcing, which led to inefficient working and deterioration of the plant without opportunity for laying off for repair. In view of the urgency of the matter he sent in an interim report in February urging immediate boiler extension. He gives a full description of the plant, and condemns very strongly the condition of the mechanical stokers, forced draught plant, flues, economisers, &c., and comments on the unsuitable quality of coal used. With regard to the allocation of responsibility, Mr. Lacey considers that had it not been for difficulties with the Local Government Board which prevented Mr. Barnard's advice being adopted, the undertaking would not have sustained the heavy financial losses of the past 12 months. The most serious of the difficulties were due, he considers, to causes beyond the control of the committee or of the Electrical Engineer. Repairs were recommended to the auxiliary, as well as the provision of a new boiler at a total cost of about £5,200. In general, however, Mr. Lacey reports that the site of the station is unsuitable, the design of the station is bad, and the only proper way to provide for the future is to erect forthwith a new 3,000 kw. station, capable of ultimate extension to 12,000 kw. In the meantime increases in the tariff are recommended.

Mr. Barnard in his remarks points out the very heavy strain put on the station, and discusses the condition of the plant in some detail to show that Mr. Lacey's remarks that "there were causes for the apparent negligence," which were beyond the control of the station staff. At the same time, he complains that his staff was inadequate, that he was never allowed to have a fully qualified chief assistant, and that his recommendations as to the control of the station during his six months' illness were not followed.

The Electricity Committee, in considering these reports, are unwilling to free the engineer entirely from blame regarding the unsatisfactory condition of the plant, but approve of the retention of his services, pending the result of the present year's working being known. A Works Sub-committee is appointed to keep a watch on the matter. Some of the immediate recommendations of Mr. Lacey have been carried into effect, and a

reorganisation of the staff has been made. Having regard to this provision of additional boiler plant, the question of a new station is shelved for the present, and other matters in Mr. Lacey's report are still under consideration.

## ELECTRICAL EQUIPMENT AT AN ASYLUM

THE self-contained electrical equipment of the new Severalls Asylum at Colchester is interesting on account of its completeness. Electricity is used for lighting and power throughout the premises. The engine-room is 51 ft. long, 36 ft. wide, and 15 ft. high. The interior walls are lined with white glazed brick relieved with a dado of green. There are three Paxman engines, supplied with steam at 120 lb. per sq. in. from dry-back boilers. Two drive 100 kw. compound dynamos giving 470 volts at 450 r.p.m., and the other drives two 50-kw. machines forming a steam balancer. There is also a motor balancer consisting of two 235-volt 15-kw. machines. No battery is at present installed, but provision is made for one to be added at a future date. The main switchboard is placed at the end of the engine-room. It consists of marble slabs mounted on an iron frame let into the end wall, and is raised about 6 in. from the floor, and is protected by a hand-rail. Plant, switchgear, and travelling crane were supplied by the British Thomson-Houston Co., Ltd. (Rugby). The heating and hot-water supply is furnished by the exhaust steam from the engines at about 5 lb. per sq. in. to calorifiers which are also fed with live steam through reducing valves. The steam-pipes, valves, &c., were supplied by Aiton and Co. (Derby). The Asylum buildings are constructed in the form of a large rectangle with several spur wings, and the wiring is carried out through a subway about 8 ft. wide by 6 ft. 6 in. high, which runs under the whole of the rectangular portion, with creepways under the wings. From the switchboard feeders are carried to a triple concentric ring main running the whole length of the subway and supported in wooden cleats bolted to the walls. Some of the larger services are connected as three-wire and the remainder as two-wire. The supply pressure is 460 and 280 volts. Special mains supply the covered ways, connecting the various blocks with two distinct services, and others supply power to the laundry, bakery, &c. Twin lead-covered wires are used for the lighting of the covered ways, and the general wiring is carried out in wood casing with covers in the form of a circular arc, so that the lodgment of dust may be a minimum. Plain pendant fittings are used as much as possible, with a specially designed bulkhead fitting for the single rooms and batten-holders in the covered ways and subways. Two-way switching is employed, so that the night watchman can switch on a section as he approaches, and off as he passes through. All the water required is pumped by electric motors, and two 20-h.p. fire-pump motors are also installed. A 8-h.p. motor in the bakery is used for the kneading and mixing machines, while over 50 h.p. is supplied by four motors for the washing and drying machines in the laundry. Others will be added as required. The motors were supplied by Mawdsleys, Ltd. (Dursley).

In addition, a central battery telephone system, a fire alarm, and a central time recording system is installed. The complete wiring was carried out by H. J. Cash and Co. (Westminster), while the consulting engineer for the whole scheme was Mr. W. C. C. Hawtayne (9 Queen Street Place, E.C.), to whom we are indebted for these particulars.

**The Ghent Exhibition.**—A preliminary list of the British exhibitors has been issued by the Board of Trade Exhibitions Department. Among electrical and engineering firms that are represented may be mentioned the British Westinghouse Co., Ferranti, Ltd., the Harper Electric Piano Co., R. O. Lister and Co. (Dursley), Reavell and Co., Sanders, Rehders and Co., and Vickers, Ltd.

**The "Point Fives."**—The discussion at the meeting on June 17th at the Delico Restaurant will be opened by Dr. Ferranti. Several general points were unanimously agreed after the debate on the standardisation of electric cookers at the special meeting on May 23rd. These were: (a) that cooking ranges (consisting of oven, with at least two circuits, grill, and hot-plates) should have each subcircuit separately fused, and each protected by a switch; (b) switches and fuses should be easily accessible, and so positioned that they cannot be unduly heated or damaged by liquids; (c) provision should be made for efficient earthing; (d) at least one separately-fused indicating device to show whether any circuit is closed should be fitted; and (e) manufacturers and designers should endeavour to develop a hot-plate which will work satisfactorily at a red heat. It was not found practicable in the time available to come to any decision on the subject of tariffs. Further consideration of this subject was therefore deferred to a future meeting.

## British Association Reports on Electrical Standards

## A "TRICITY" COOKING OUTFIT

BY the courtesy of the British Electric Transformer Co., Ltd., we are able to illustrate here a "Tricity" cooking equipment which is in use at the house of Alderman J. P. Smith (Chairman of the Electricity Committee, Barrow-in-Furness). In addition to the apparatus shown in the illustration, there are two more single cookers which can be used on

'TRICITY' COOKING EQUIPMENT IN A PRIVATE HOUSE.

a table placed in front of the kitchen range, controlled by two panels similar to those shown in the illustration. These are for either heating an urn or for grilling operations. The hot-water supply of the house is taken care of by an independent coke stove which has been fixed near the kitchen range. The installation has only recently been completed, but we understand the average consumption for cooking for a household of five adults is 8 units per day. During the second week in May, Mr. F. S. Grogan, of the British Electric Transformer Co., Ltd., gave a series of lectures and demonstrations, and the Corporation of Barrow-in-Furness have decided upon a scheme for hiring out "Tricity" cooking outfits to their consumers.

**Shipping Exhibition.**—A Shipping, Engineering, and Machinery Exhibition is to be held at Olympia in the autumn of next year. Arrangements are being made whereby the exhibition will be run on co-operative lines by the industries concerned, and several large shipping and engineering firms have already promised support. The organising managers are Mr. C. H. Luke and Mr. F. W. Bridges.

**The British Electrical and Allied Manufacturers' Association.**—The Wilson-Wolf Engineering Co., Ltd., and Tilghman's Patent Sand Blast Co., Ltd., have been elected Members of the Association, while Maschinenfabrik Augsburg-Nürnberg A.G. has been elected an Associate.

**"The Central."**—The May issue of the magazine of the old students of the City and Guilds (Engineering) College, South Kensington, contains an interesting article entitled "Some Notes on the Present Position of Electric Traction," by Mr. L. Calisch. This is an illustrated second instalment—the first appeared in *The Central* for August, 1912. Among other articles may be mentioned one on "Precise Surveys for Tunnel Alignment," by Mr. J. L. Busfield, and one on "The Development of the Æsthetic Sense in Engineers," by H. E. A. This deals largely with lead paints, and is written in humorous vein. A large number of personal and general notes are also included.

## NEW ENCLOSED FUSES

A NUMBER of important improvements in the design of enclosed cartridge fuses have been embodied in the "Rex" totally enclosed fuses, which are made and supplied by the General Electric Co., Ltd. (67 Queen Victoria Street, E.C.). These fuses may be obtained for 2, 4, 6, or 10 amperes capacity at 250 or 550 volts at a very moderate price. The

neatness of the design is seen from the illustration, which shows a 10-ampere 550-volt size. All the metal parts are shielded, and fuses of one capacity are not interchangeable with those of another capacity. An efficient indicating device is provided, and, owing to the sealing arrangements, no

explosion or arc ensues, even on a dead short. They may be obtained made up on distribution boards in wooden or iron cases, and a design suitable for use in existing spring clip fuse boards, with  $2\frac{1}{2}$  in. break, is also available. An allowance for blown fuses is made by the company. Descriptive leaflets dealing with these fuses are now obtainable on application.

**Factory Lighting.**—The Home Secretary has appointed Professor C. S. Sherrington, F.R.S., D.Sc., of Liverpool University, to be an additional member of the Departmental Committee on the lighting of factories and workshops.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,341.

A system of discriminating fault protection has been recently developed in which the difference under fault conditions of the currents flowing in two concentric conductors in parallel, and normally equal, is utilised to trip the switch. It is desired to apply this system to three single concentric cables in parallel originally laid for A.C. single-phase distribution, but now required to be converted to three-phase as feeders. What are the objections to this arrangement, and what is the formula for mutual induction of the cores (1) when currents are equal and in the same direction; (2) when one current is larger than the other, but both in the same direction; (3) when one current is in the opposite direction to the other? What would be the effect of a stray field on each core; for instance, how would the voltage induced in the cores compare if a length were suddenly drawn sharply through a magnetic field?—"KINK."

(Replies must be received not later than first post, June 12th.)

### ANSWERS TO No. 1,337.

**Coal Mines Act Electrical Rules:**—Rule 14, C (1), requires "the thorough examination of all apparatus (including the testing of earth conductors and metallic coverings for continuity) as often as may be necessary to prevent danger; and (2) the examination and testing of all new apparatus, and of all apparatus re-erected in a new position in the mine before it is put into service in the new position." Under ordinary circumstances how often will it be advisable to test earth conductors and metallic coverings, and what other "examination and testing" is necessary on the following plant? How may we prove that we have continuity and suitable carrying capacity of all armour and earth conductors? We have two 2,000-kw. generators, 3,000 volts, 40 cycles, three phase; current is transmitted at this pressure to three seams at different depths. In these seams we have haulages working direct at 3,000 volts; also in each seam we have transformers stepping down to 440 volts for pump motors and small haulage, and small lighting transformers 440 to 110 volts. The cable from the H.T. switch-board in the power-house to each seam is three-core, paper-insulated, lead-sheathed, and double-wire-armoured; it is fixed to sides of shafts by wooden cleats, and the shaft is comparatively wet. We use the lead sheath and armour as our main earth connection to surface earth plate. The shaft cable is led to a distribution board in each seam, from which all cables in use are also double-wire armoured, and the armour in every case is used as main earth wire between each motor, &c., and main cable armour to surface. I may mention here that in some places the cables are buried in the ground. We have two C.I. earth plates at the surface, and one in the sump at each seam. We transmit about 600 kw. into each seam. The depths of the seams below surface are 400 yards, 500 yards, and 680 yards. At each motor we connect up the switch, controller, motor frame, &c., to a common copper earth wire, and this to armouring of cable by means of W.I. clamps, as, of course, we cannot solder terminals on here underground.

"ASSISTANT ELECTRICIAN."

The first award (10s.) is made to "C. L.," and the second award (5s.) to "Colliery Electrician." We publish these in slightly abridged form. Reference should also be made to

ELECTRICAL ENGINEERING of August 15th, 1912, p. 457, in which a set of 12 rules, to be issued by the mine manager to the working electrician-in-charge, is suggested.

### QUESTION No. 1,337. ANSWER.

"C. L." writes:—The electrician ought to examine all plant at least once in every week, as follows:—

Follow the main cable in-by, and see that all suspenders or other fastenings are intact; examine each joint-box carefully, and, by taking hold of the earth wire that connects the armouring at each end of joint box with the fingers, satisfy yourself that this is secure, and if necessary tighten screws with screwdriver. All earth wires of motors and apparatus should also be tried as above, as they are liable to work loose.

Oil switches should have their baths removed at least once in every month, the period between each inspection depending upon the purpose for which the switch is being used. The oil should be tried by dipping the hand in and scraping fingers along bottom of bath; if the oil is thick or of very dark colour, and if any residue is at the bottom, the bath must be cleaned and the oil filtered or renewed. Liquid controllers should have part of the liquid renewed every fortnight.

Metallic controllers should be inspected every fortnight at least (in the case of large units every week), and burnt contacts renewed or dressed up with a file.

To prove metallic continuity of earth wires to bank, unfasten the main connection of earth wire and armouring that forms the earth to bank at both ends of main intake cable. With the current "off," short-circuit one conductor and armouring, and test as in Fig. 1 from the other end with an accumulator battery. The resistance of the armouring will be  $\frac{V}{A}$  less the resistance of one core of the cable. [A better way is to

Fig. 1.

Fig. 2.

connect as Fig. 2, when the resistance of the armouring is simply  $\frac{V}{A}$ —Ed. E.E.]

Assuming a competent electrician in charge, a test for continuity of earthing system to bank need only be made about every three months. The Rules demand that conductivity of the earth wire shall be not less than 50 per cent. that of the largest conductor used solely to supply apparatus a part of which it is desired to earth. Therefore, in the event of H.T. current transformed down to L.T., it may be found necessary to run an extra earth wire if the conductivity of earthing system to bank is to be kept within legal limits. Although the lead sheath may be connected to armouring, the lead cannot be reckoned in when estimating the conductivity of armouring.

In addition to an insulation test of motors, a feeler gauge test of the air-gap should be made at least once in every week. An "Inspection Book" ought to be kept, and the results of the systematic inspections entered up in it, e.g., gap, top 30, bottom 25, say. When a belt drive is used, the feelers ought to be inserted into that part of the gap which the belt pull tends to reduce. Brushes of D.C. machines should be carefully examined, and renewed in the case of tips being broken off. Switches ought to be tried for tension, as insufficient "tension" will cause heating of contact surface. Large transformers of the oil type should be "sludged" occasionally, and the oil tried for moisture. This can be done by taking a sample of oil in a glass jar and inserting a red-hot piece of, say,  $\frac{1}{4}$ -in. iron; if moisture is present there will be a crackling noise. Lightning arrestors should be examined and kept clean.

All new apparatus ought to be efficiently earthed and tested for insulation resistance by a "Megger," and a final inspection

of oil baths made to be doubly sure that these are at the correct level.

"COLLIERY ELECTRICIAN," who is electrician of a modern three-phase colliery plant, describes the methods adopted there in endeavouring to comply with Rule 14, Section C 1 and 2, as follows:—

We examine all oil-immersed gear, such as motor control switches, controllers, and resistances, weekly. A record is kept of condition of same, and also of the state of the oil; the oil is changed at intervals. This examination is made on night duty, a few motors being examined each night. The condition of the slip-rings and brush-gear is also paid attention to, and rotor clearances are taken monthly.

An insulation test is taken of the whole system monthly. Each section taken by itself from the low-tension board in the transformer house. The procedure is as follows:—The supply is cut off from the section, and then the switches at the various motors are put in, and the controllers put on *first step*, which, of course, allows us to test through whole of resistance and motor.

For testing continuity of cores and armouring we obtain the information by "looping," at the farthest-away motor in the section, the core of cable to the *earth wire*, which is clamped on to the armouring.

New apparatus undergoes an examination in the shop before coming down the pit, and the motors are given a twenty-four hours' running test on a testing bed. All this material is tested for soundness of insulation and continuity.

### OIL SWITCHES WITH ISOLATING DEVICES

THE illustration shows a new form of oil-switch suitable for wall mounting and containing an isolating device, which has been designed by A. Reyrolle and Co. (Hebburn-on-Tyne). The isolating switch handle mechanism is interlocked with the oil-switch to ensure that, when the circuit is broken, it must be broken on the oil-switch, avoiding any risk of arcing on the isolating contacts. Suitable provisions are made for receiving cables to accommodate the equipment on which the panels are used. The cables may be arranged to lead

in and out respectively in a vertical position, as shown on the illustrations, or, in other cases, suitable provision is made for leading the cables out horizontally.

Like all of Messrs. Reyrolle's manufactures, the workmanship is of good quality, and the new combination serves very well in place of an individual switch panel for controlling a motor in a situation remote from the power plant, where the more expensive draw-out type pillar, for economic reasons, cannot be installed.

### AN UP-TO-DATE CONDENSING PLANT

THE surface-condensing plant supplied by the Mirreles-Watson Co., Ltd. (Scotland Street, Glasgow) for the 3,000-kw. turbo-alternator which forms the latest addition to the plant at the Pinxton power station of the Glasgow Corporation Tramways, contains several interesting features. It is designed to deal with 72,000 lbs. of steam per hour, at which duty it is capable of giving a 28-in. vacuum when supplied with cooling water at 70° F. The condenser is of the wedge-shape type, without baffle plates, and has 10,200 sq. ft. of cooling surface, which allows considerable margin for loss of heat transmission, due to scaling or dirty tubes. The circulating water passes three times through the full length of the tubes. The Mirreles-Leblanc rotary air and condensate or water-extracting pumps and the centrifugal circulating pump, are directly coupled to a 120-B.H.P. "Curtis" steam turbine, running at 2,000 revs. per minute. The water-extracting pump is capable of withdrawing the water from the condenser under the highest possible vacuum, and delivering it to a "Lea" recorder tank. The circulating water pump is capable of delivering 6,000 galls. per minute against a total head of 20 ft. On account of the high speed of the turbine drive, the impellers are of small diameter, and to pass the quantity of water required, six of these are mounted on a common spindle, where they work in parallel. The efficiency of this pump is 62 per cent. These rotary pumps, with their turbine, form a very compact group and the running is practically noiseless. There are only the revolving parts of the turbine, the pump spindle and impellers, as no gearing whatever is required.

### CATALOGUES, PAMPHLETS, &c., RECEIVED

**SWITCHGEAR.**—A series of leaflets conveniently bound in one cover describe some of the latest products of A. Reyrolle & Co., Ltd. (Hebburn-on-Tyne). The apparatus dealt with much of which has already been illustrated in our columns, includes "split conductor" protective gear under the Merz-Price patents, sheet-steel enclosed generator panels, cable glands and fittings for armoured cables, armoured wall operated switch-gear, plugs and sockets, cast-iron distribution boxes, &c.

**ROLLER BEARINGS.**—A neat booklet dealing with "Timken" adjustable roller bearings is now being distributed by The Electric & Ordnance Accessories Co., Ltd. (Cheston Road, Aston, Birmingham), who will be pleased to supply a copy to any of our readers who are interested. The booklet sets forth in clear and concise manner the weak points of ordinary ball bearings, and explains how the design of the "Timken" bearing gives it advantages over some other roller bearings on the market by the arrangements for always securing parallel-line contact, and the care taken in the accuracy of manufacture of the constituent parts combined with careful choice of materials which are subjected to special hardening treatment.

*Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."*

**SWITCHGEAR.**—We have received from the Midland Electric Manufacturing Co., Ltd. (Rea Street, South Birmingham), a comprehensive catalogue of ironclad switches and fuses, motor control panels, distribution wards, fuses carriers, knife and other quick break switches, switchboards, &c. A very ample range is presented, and the prices throughout appear very moderate.

**CLUTCHES AND GEARING.**—A new catalogue from David Bridge & Co., Ltd. (Castleton Ironworks, Manchester), describes Heywood & Bridges' patent friction clutches, and illustrates a considerable range of pulleys, gearing, shafting, flexible couplings, and millwright work generally. Some useful tables are also included.

**METERS.**—A full description of the "Fortiter" continuous-current watt-hour meter is given in an illustrated booklet from the Union Electric Co., Ltd. (Park Street, Southwark, S.E.). This contains some interesting special features, notably as regards the design of the brush gear, the patent locking device, and the ease of access to all vital parts without removing the cover.

**The Electrical Trades Benevolent Institution.**—Sir William Preece has promised to add his name to the list of donors for £100 each. The number has therefore now reached five, leaving five more donors yet to be found for the conditions of the original donation to be fulfilled.

## TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

INTERESTING details of the *Telefunken* quenched spark system as supplied to ships are contained in a new illustrated pamphlet from Siemens Brothers and Co., Ltd. (Woolwich). The manufacture of this apparatus was commenced at Woolwich in 1910, and a large number of British and foreign vessels have been equipped. Recent contracts include eleven ships of Messrs. A. Holt and Co., seventeen ships of the Tank Storage and Carriage Co.'s fleet, as well as some long range foreign naval installations and land stations, including those of the British North Borneo Co. and the African Direct Telegraph Co. From statistics which are given, it appears that of the total number of wireless stations throughout the world more than fifty per cent. are equipped on the "quenched spark" system, in which an efficiency of 50-75 per cent. is stated to be obtained in transforming the primary electrical energy into useful radiated energy. This has led to the classification of the types of station according to the energy in the antenna, and not according to the

SIEMENS STANDARD TELEFUNKEN 0.3 kW. SHIP SET.

primary energy. Thus a 15-kw. installation of the usual open-spark type with an efficiency of about 30-35 per cent. has only the same radiative power as a quenched spark 5-kw. installation. Other advantages of this system are also pointed out, such as the harmonic nature and high pitch of the propagated waves, which enables atmospheric disturbances to be largely eliminated; the absence of noise which, with the ordinary spark gap, necessitates a specially constructed sound-proof cabin occupying a considerable amount of valuable space on board ship. The standard ship equipments range in six sizes, from the extremely compact 0.1 kw. launch equipment, with a range of forty miles by day, to the large 5-kw. ship or shore plant, with a 500-mile day range. One station which has been specially designed to meet the requirements of the recent American Shipping Acts, and has a

guaranteed range of 100 miles by day, is totally enclosed in a roll-front case, of which the dimensions are only 4 ft. 8 in. by 2 ft., 2 ft. by 2 ft. 4 in. This is illustrated in the figure. Where there is an electric installation, the requisite direct-current (about 400 watts) can be taken from the ship's mains. If no electric installation is available, the necessary energy is provided by a D.C. generator of about  $\frac{1}{2}$ -kw. output, driven by a petrol or other engine. The transmitter includes a special high-tension induction coil feeding the excitation circuit. This consists of a battery of Leyden jars, an inductance of copper strip, and a quenched spark gap. An aerial lengthening inductance of two fixed coils and one movable coil is provided. Fine adjustment of the wave-length emitted is obtained by adjusting the position of this movable coil. An aural receiver with contact detector is employed. This receiver, which has a wave-range of from 200-2,000 metres, provides a wide range of variation of coupling, enabling very exact tuning to be obtained.

There seems to be considerable difference of opinion among the members of the House of Commons Committee which has been inquiring into the Imperial wireless telegraph scheme as to the nature of their report. Not only is it stated in *The Times* that a separate report has been prepared by the Unionist members of the Committee, but also certain Liberal members of the Committee favour a report in which no reference is made to the dealings of Ministers in American Marconi shares: on the other hand, it is believed that the Chairman of the Committee, who is also a Liberal, is not in favour of this course being taken.

The Compagnie Française des Câbles Télégraphiques is in trouble again, as the Paramaribo-Cayenne cable failed on 28th May. This misfortune was followed by another on the 30th May, when the Martinique-Paramaribo cable also gave out.—The Meshed line gave out on the 3rd inst. near Teheran.

## ELECTRIC TRACTION NOTES

The London Suburban Traction Co., which, as we recently announced, has been formed to amalgamate the Metropolitan Electric Tramways, Ltd., and the London United Tramways, Ltd., has now acquired a controlling interest in the South Metropolitan Electric Tramways and Lighting Co. Thus, with the exception of the London County Council Tramways, the whole of the tramway and motor-bus services in the Metropolitan area are now under one control.

The British Electric Traction Co.'s finances are beginning to show signs of considerable improvement. For the year ended March 31st, 1913, after paying the full 6 per cent. dividend on the first preference stock, a 8 per cent. dividend is also to be paid on the non-cumulative 7 per cent. preference stock. The receipts for the year were £50,000 better than in the previous twelve months, whilst for the current year to date the receipts are £6,800 better than for the corresponding period last year.

The Sunderland District Electric Tramways Co. is now out of the hands of the receiver, and the financial position is much stronger. It is proposed to reduce the share capital and to write off the debit balance, and a proposal to this effect will be placed before the shareholders later on.

Several London Borough Councils are threatening opposition to the Bill of the Postmaster-General for constructing a tube railway through London, on the ground that sufficient protection is not given in regard to the electric mains.

The Sunderland Corporation has agreed to arrange mutual running powers with the Sunderland District Tramways Co.

A deputation of the Edinburgh Corporation has been visiting various places in England where "self-propelled" tram-cars are in use. Included in their tour was London, where the Stevens petrol-electric cars of the London County Council were examined. As the result of its inquiries the deputation has reported that the introduction of some form of self-propelled car for Edinburgh experimentally is justifiable.

As the result of the decision of the House of Commons last

# "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

## Specifications Published May 29, 1913

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

8,040/12. **Induction Motor Control.** SIEMENS-SCHUCKERT. To adjust the speed by varying the frequency and pressure of the power current a self-excited series connected commutator generator is connected to a transformer through a choking coil, saturated so that as the frequency of the generator is reduced by altering the ratio of the stator and rotor pressures, the effective magnetic characteristic simultaneously drops, so that stable pressures are produced approximately proportional to the frequency. A transformer with adjustable secondary in parallel with the stator may also be added to the mains. Four figures.

11,051/12. **Remote Controlled Switches.** A. H. F. PERL. On the control circuit being closed a magnet is energised, and this attracts an oscillating armature which is arranged to break the circuit just before the mid point of the swing is reached, so that it is carried by its own momentum, aided by a spring, to its position for the next operation. The switch is worked by a pin on the armature connected by a crank to a rod engaging the shorter arm of a switch contact lever. Two figures.

12,444/12. **Wireless Receiving Stations.** D. ZAHARIA and G. ROTHLÄNDER. The telephone is arranged directly in a detector circuit which has a unipolar connection with the primary circuit. Increased pressure is thereby obtained in the detector circuit similarly as in a radiation coil. The primary winding is bridged over by a regulating resistance. Four figures.

**Wireless Telegraphy.** H. SEFTON-JONES (*Ges. für Drahtlose Telegraphie*). High frequency currents are obtained by supplying current to static frequency transformers with a frequency of at least 5,000, obtained from a high-frequency alternator. The frequency may be further increased by sending the secondary high frequency current through the primary coils of the same transformer. Tuning means may be inserted in the secondary circuits, and a pressure adjusting transformer may also be inserted. In order to allow of higher saturation than usual the windings of the frequency transformers are smaller than usual, and the transformer is placed in a cooling and insulating liquid. Four figures.

15,342/12. **Sealing Wires in Glass.** B. T.-H. Co. (*G. E. Co., U.S.A.*). Iron chromium alloys containing from 20 to 30 per cent. of chromium have been found to have the same temperature coefficient as lead glass, and to adhere to the glass so as to make a perfectly vacuum tight seal.

17,357/12. **Loud Speaking Attachment for Telephones.** H. W. PRANCE. A trumpet is placed in front of a platform provided with guides, so that when the telephone receiver is placed on the guides it slides into position with the diaphragm coincident with the small end of the trumpet.

22,500/12. **Self-Regulating Dynamos.** J. POLKEY and GEO. POLKEY, LTD. A single intermediate brush approximately midway between the main brushes bears on the commutator. The field winding is in two parts, one part, half on each of two diametrically opposite poles, is connected between one main brush and the intermediate brush. The other part is placed on one pole only, and is connected between the other main brush and the intermediate brush. Two figures.

25,090/12. **Lead Alloys for Tapes.** W. E. Co. (*W. E. Co., U.S.A.*). The tapes are primarily intended for telephone switch-board cables. It is stated that by using an alloy composed of 93.25 to 96.75 parts lead, 3 to 6 antimony, and 0.25 to 0.75 of one part tin, the tape need only be about half as thick as usual, with pure lead tapes to obtain equal strength.

27,813/12. **Incandescent Lamps.** M. SIDON. The filament carrying frame is removably mounted on a conducting rod supported in the base of the bulb. The rod is adapted to hold the parts in place and to connect the filament to the leading-in wires in such a manner that the frame may be removed without breaking them. Five figures.

28,627/12. **Series Arc Lamps.** W. ROGERS and G. ROWE. A pivoted and adjustable stop-piece and an auxiliary pendent armature which will fall away from the lamp spool on cessation of the current, are so arranged that the fall of the lamp armature is prevented until the arc of any of the series lamps becomes too long. All the top carbons fall at the same instant and strike fresh arcs. Three figures.

29,848/12. **Negative Electrodes for Alkaline Storage Cells.** H. P. R. L. PORSCHKE and J. A. E. ACHENBACH. To increase their capacity, negative electrodes for alkaline accumulators are made by boiling finely powdered iron and cadmium in an excess of ammonia water until a dry mixture of metal powder and metal compounds is obtained. This is subjected to a reducing electrolysis in an alkaline solution.

6,479/12. **Transmitters for Wireless.** J. SAHULKA. By means of a rotating commutator the pressure across the condenser in the oscillation circuit is kept equal to twice the pressure of the supply, so that the energy absorbed by the condenser is increased fourfold. Seven figures.

## Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

**Dynamos, Motors, and Transformers:** DARMOIS and LEBLANC [Vapour rectifiers] 11,870/12; SCHNEIDER [Bi-polar form-wound rotor windings] 12,766/12; PLOHL [Magnetic and electric fields for frequency changing] 15,774/12.

**Electrometallurgy and Electrochemistry:** RUSS and EHRLICH [Oxidation of mixed nitrogen and oxygen] 10,992/12; DUBILIER [Ozone] 11,090/12; PEACOCK [Compounds of aluminium, carbon, and nitrogen] 11,393/12 and 11,395/12; PROSTLER and GES. FÜR ELEK. INDUSTRIE [Sheet brass and aluminium welding] 25,987/12.

**Heating:** STOTT and SCHOFIELD [Water] 10,955/12; PURLE, 15,429/12.

**Ignition:** SCOTT [Engine starter combined with car-lighting set] 11,388/12; BOSCH [Distributor] 5,532/13.

**Incandescent Lamps:** TRIQUET [Mercury vapour] 12,270/12.

**Meters:** H. ARON ELEKTRICITÄTSAHLERFABRIK [Motor] 792/13.

**Switchgear, Fuses and Fittings:** COOPER [Manufacture of resistance bodies] 11,380/12; PILLINGER and SUNDERLAND [Switch] 11,486/12; HUNTER and SHAND [Switches] 11,586/12; NICHOLSON [Relays] 30,059/12.

**Telephony and Telegraphy:** MELLINGER [Telephony] 11,964/12; GOTT [Telegraph cable working] 22,364/12; ROOSE and FINLAY [Selective signalling] 28,486/12.

**Traction:** STITT [Railway signalling] 12,649/12.

**Miscellaneous:** PRICE [Automatic electric thermal control] 15,178/12; GIBBS [Protective layer on iron electrodes] 15,852/12; JABS [Clocks] 24,313/12; GRAEMIGER [Electromagnetic suspension devices] 24,499/12.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Distributing Systems, &c.:** SIEMENS SCHUCKERT [Flywheel storage for hauling or winding engines] 11,007/13.

**Electrochemistry:** SOC. GEN. DES NITRURES [Aluminium nitride manufacture] 10,975/13.

**Switchgear, Fuses and Fittings:** HOVLAND [Relays] 10,472/13; A.E.G. [Automatically maintaining phase equality in parallel machines] 10,609/13.

**Telephony:** SIEMENS & HALSKE, 10,685/13.

**Traction:** MOUYEN [Railway signalling] 10,803/13.

**Miscellaneous:** HARTMANN & BRAUN [Measuring small resistance variation or differences] 8,602/13.

## Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

**Arc Lamps:** JOHNSON & PHILLIPS and S. PATERSON [Non-shunt lamps for series working] 3,266/08.

**Dynamos, Motors, and Transformers:** B.T.-H. Co. (*G.E. Co., U.S.A.*) [Single-phase commutator motor speed control using transformer] 3,588/04; B.T.-H. (*A.E.G.*) [Single-phase commutator motors for machine-tool driving, and having a shunt characteristic for the working period and a series characteristic for the idle period] 3,096/08.

**Incandescent Lamps:** H. HOGE and "Z" LAMP Co. [Metal filament lamp] 3,248/08.

**Instruments and Meters:** H. BEVIS and J. W. PENICUD [Recording galvanometer recording simultaneously currents in three circuits] 20,633/08.

**Storage Batteries:** P. MARCHAL [Charging apparatus] 3,494/08.

**Switchgear, Fuses, and Fittings:** B.T.-H. Co. (*G.E. Co., U.S.A.*) [Remote control switchgear] 3,666/04.

**Telephony and Telegraphy:** SIEMENS & HALSKE [Selectors for single-line working] 2,308/08.

**Traction:** F. E. CASE [Multiple unit control: contactors worked by currents of different strengths obtained by resistance regulation through the master controller] 18,331/01; B.T.-H. Co. (*G.E. Co., U.S.A.*) [Series parallel control: contactors are operated against control by a cam shaft] 3,886/04.

**Miscellaneous:** G. H. DAVIS [Automatic piano players and music recorder] 3,617/02; W. REUTER [Electromagnet for loading conveyers, cradles, &c., piece by piece] 3,737/04; B. F. HUTCHES [Electro-mechanical typewriter] 3,355/07; SIEMENS BROS. (*Siemens & Halske*) [Motor-car horns] 3,778/07.

week, giving the London Borough Councils the same veto for trolley-bus schemes that they have over tramways schemes, the L.C.C. has withdrawn from its Tramway Bill this session four trolley-bus schemes in Hackney and Sydenham.

In consequence of the success of working trailer cars in the Woolwich district the L.C.C. has asked the Board of Trade to sanction their use upon the Merton circular route.

The scheme for the construction of an electric tube railway between Stokes Bay, in Hampshire, and Ryde (I.O.W.), is being revived. Some years ago a similar scheme was actually sanctioned in an Act of Parliament, but the capital for its construction was never raised.

A holder of £11,000 ordinary stock in the Metropolitan Railway Co. has deposited a petition in Parliament against the Bill of the Company, which seeks to purchase the Great Northern & City Tube Railway.

Referring to last week's note on the locomotives for the Loetschberg tunnel, on page 309, we have received a letter from Mr. W. Gratwicke pointing out that the ten new locomotives are not quite of the same design as the Oerlikon locomotive illustrated, with which the trials were made. They will be, he says, of the ten-coupled (2-10-2) type, with a total weight of 108 tons, of which 85 will be available for adhesion. Each of the two motors, which are geared to jack-shafts driving through cranks, will develop 2,500 h.p. at 50 km. per hour for 1½ hours, and will exert a pull of 180,000 kg. at starting.

## LOCAL NOTES

**Abercarn: Electric Lighting.**—The Board of Trade has refused to grant the Council an electric lighting order.

**Blackburn: Electricity Accounts.**—The net profit of £3,521 upon the electricity undertaking last year is nearly double that of the previous twelve months. About 1,500 looms having individual motors are now driven from the Corporation supply mains, and there are now 5,000 h.p. of motors connected.

**Cleckheaton: Bulk Supply.**—The Council, which has an electric power station of its own, is negotiating with the Yorkshire Electric Power Co. for a supply of electricity in bulk.

**Coventry: Electricity Profits.**—The net profit on the electricity undertaking for the year to March 31st was £16,245. A sum of £4,500 is to be paid in relief of rates and £11,600 to plant reserve. The flat rate for lighting purposes is to be reduced from 4½d. to 3½d. per unit.

**Dundee: Electricity Accounts.**—The accounts of the Corporation Electricity Department for the year ended April 30th, 1913, show a net profit of £7,082. The increase in the sale of units is between 1½ and 2 million, representing an additional revenue of £4,000. The bulk of the progress during the year has been in the direction of power supply, although there has been the gratifying increase of 250,000 units for lighting purposes. The whole of the profit has been allocated to the reserve fund, bringing this to £21,000, and as this fund has been built up in three years, this result must be considered exceedingly satisfactory.

**Exeter: Electricity Accounts.**—There was a net surplus of £1,378 on the Electricity Department last year, in spite of the fact that the tramway supply was less by 21,000 units than in the previous twelve months. Although the charges for power and heating have been twice reduced recently, the loss of revenue from this cause has been already counterbalanced by the increased demand. The Electric Light Committee recommends placing the surplus to reserve and renewals account.

**Grimsby: Electric Lighting Accounts.**—In spite of the loss of the Railway Co.'s custom, which amounted to £2,100 per annum, the net profit for the past year was £3,147. This result is due to the very large development in private supply. The sum available after meeting various charges, apart from capital charges, is £1,417, and Mr. W. A. Vignoles, the Borough Electrical Engineer, in his report, urges the Committee to take the whole financial position of the undertaking into account before deciding what shall be done with this sum. The desirability of a strong reserve fund is pointed out, but nevertheless Mr. Vignoles suggests that part of the surplus might be utilised to pay off the amount still owing to the rates in respect of contributions received in the first three years' working of the undertaking. The Electric Light Sub-committee recommends that £1,330 10s. be transferred to the relief of rates, and expresses the hope that within the

next few years they will be able to repay compound interest on the money received from the rates.

**Manchester: Electricity Accounts.**—The accounts just published show a revenue of £467,194, compared with £427,701 in the previous twelve months. A sum of £24,500 is to be transferred to relief of rates out of the net profit. The cost of coal during the year was 12s. 4d. per ton, compared with 10s. 10d. in the previous year, but the average working costs were 1'033d. per unit sold compared with 1'045 in 1911-12.

**West Ham: Electric Battery Vehicles.**—Following the example of Glasgow and one or two other places, the Electricity Department has invested in two Edison battery vans for departmental work.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

### Generating Stations, Sub-Stations, Mains, &c.

**Atherton.**—A loan of £6,800 for electric lighting extensions is to be taken up.

**Bispham.**—Sanction of the Local Government Board has been given to the borrowing of £8,155 for additional plant.

**Dolgelly.**—A committee has been appointed to arrange for a site for an electricity generating station.

**Halifax.**—A loan of £23,180 has been sanctioned for electrical extensions.

**Hebden Bridge.**—An inquiry has been held concerning a loan of £3,250 for electrical extensions.

**London: Hammersmith.**—Air-cooled static transformers. (See advertisement on another page.)

**Marylebone.**—A loan of £42,500 is to be taken up for electric lighting purposes.

**Southwark.**—A loan of £29,464 for new plant is to be applied for.

**Manchester.**—An inquiry was held last week concerning a loan of £75,000 for electricity purposes. There was some opposition from the Ratepayers' Association, which has decided to oppose all such applications on the part of the Corporation until there is, what they term, a more ample return on capital outlay, and proper provision made for depreciation. At the inquiry the representative of the Association stated that it was understood that the present extensions were sub-stations for large power consumers, and it was contended that power users have an unfair advantage over the larger body of consumers.

**Pembroke.**—Condensing plant for electricity works. Town Clerk. June 14th.

**Southampton.**—New cable is to be laid at an estimated cost of £950.

**Tullamore.**—The Council has received a report on an electric lighting scheme by Mr. L. J. Lawless, Consulting Engineer of Rathmines.

**Wallasey.**—Sanction to a loan of £65,000 for electrical extensions is to be applied for.

**West Hartlepool.**—Two 300 kw., 6,000 v., 40 cycle rotary converters, with transformers, switchgear, and connections; traction feeder, and Board of Trade panels, &c. Borough Electrical Engineer, June 14th.

**Worthing.**—Sanction to a loan of £6,750 for electrical extensions is to be applied for.

**York.**—Loans of £5,000 for mains, £1,000 for services, and £800 for motors, are to be applied for.

### Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

**Aberdare.**—Cinematograph theatre. Architect, C. H. Elford, 31 Canon Street.

**Barrow.**—New library.

**Beckenham.**—New school.

**Bradford.**—Residential school for blind.

**Blackburn.**—New fire station.

FOR  
STEAM JOINTS  
USE

JOHN HUDSON & CO.'S SUCCESSORS, Mansell St., London, E.

**Chelmsford.**—New school.  
**Crumpton.**—New technical school.  
**Edinburgh.**—New music hall adjoining Caledonian goods station, Lothian Road.—New Sailors' and Soldiers' Home.  
**London.**—Offices for Public Trustee and Lunacy Commissioners. H.M. Office of Works, Storey's Gate.  
**L.C.C.**—Electrical installation at Randall Place elementary school, Greenwich. (See advertisement on another page.)  
**Manchester.**—St. Mary's Church, Droylsden.  
**Redruth.**—Workhouse infirmary.  
**Rochdale.**—New building for Equitable Pioneers Society.  
**Southampton.**—Electric lighting of old pavilions at infirmary, Shirley Warren. Clerk, St. Mary's Street. June 19th.

#### Miscellaneous

**Aberdeen.**—The Tramway Manager recommends considerable extensions of the tramway system, estimated to cost £50,000.  
**Brighton.**—The Tramways Committee has presented a report recommending the use of double-deck trolley omnibuses on the Preston Road—New Road route. The capital cost of the scheme is put at £5,600.  
**London: L.C.C.**—50-ton electric overhead travelling crane for the Greenwich Power Station. (See advertisement on another page.)  
**South Wales.**—The Penrikyber Navigation Colliery Co. requires tenders for a twelve months' supply of electrical fittings. Secretary, Penrhiwceiber, R.S.O. Glam.

### TENDERS RECEIVED AND ACCEPTED

**Bolton.**—The tender of British Insulated & Helsby Cables, Ltd., has been accepted for cables.  
**Newport (Mon.).**—The tender of the A.E.G. Electric Co. for a 3,000 kw. turbo-generating set at £7,120, and that of the Lancashire Dynamo & Motor Co. for a 600 kw. direct-current generator at £935, have been accepted. There was considerable discussion with regard to the first tender, which, it was stated, was £1,326 cheaper than the lowest British tender. In addition, no English firm would carry out the whole of the contract, and the Council objected to dividing up the responsibility between three firms, which would have been necessary.  
**South America.**—Messrs. Siemens Bros. Dynamo Works, Ltd., have received a contract for the supply of "Wotan" pure drawn Tungsten wire lamps for a large town in South America. The lamps, which are mainly intended for street lighting, number 36,100, and the total candle power amounts to 2,117,000. The highest candle power lamp employed will be 400, and the lowest 16. The contract was decided upon after exhaustive tests.

### APPOINTMENTS AND PERSONAL NOTES

We have been asked to state that, owing to the operation of the Glasgow Boundaries Act 1912, Mr. T. C. Parsons and Mr. W. Sillery have now definitely retired from the management of the Govan and Partick Electricity Undertakings respectively.

Mr. C. G. Hamilton, who was elected Member of Parliament for Altrincham last week, is one of the Managing Directors of Drake & Gorham, Ltd.

Mr. Mervyn O'Gorman, at one time well known in electrical circles and now superintendent of the Royal Aircraft Factory, has been made a C.B.

Another of the Birthday Honours is a Knighthood conferred on Mr. Francis W. T. Brain, who was President of the Mining Association of Great Britain, 1911-12, and presided at the Conference in London during the coal strike last year. Those who are interested in the early days of the application of electricity in mines may possibly remember that Frank Brain was the first engineer to introduce electricity in a coal mine. He introduced electric signalling in a mine as early as 1866, and, at the Trafalgar Colliery in 1882, he installed the first electric pump.

Mr. A. A. Day, Borough Electrical Engineer to the Bolton Corporation, has resigned.

The Redditch U.D.C. has received 191 applications for the post of Borough Electrical Engineer.

The Aylesbury U.D.C. requires a Resident Electrical Engineer at a salary of £200 per annum.

The salary of Mr. R. M. Carr, Borough Electrical Engineer at Leek, has been increased by £25, making it £300 per annum.

Gas engine driver required. (See an advertisement on another page.)

### MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. G. Smith and Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £71 to £71 15s. (Last week, £72 5s. to £72 15s.)

**Change of Address.**—Matthew Wylie & Co., of 57 Robertson Street, Glasgow, have removed to 81-83 Portman Street, Kinning Park, Glasgow.

**Exhibition Awards.**—The British Thomson-Houston Co. (Mazda House, Upper Thames Street, E.C.) has been awarded a diploma for their display of up-to-date systems of illumination at the recent Cinematograph Exhibition.

A Diploma of Honour has also been awarded to the Electrical Engineering and Equipment Co., Ltd., for their exhibit at this Exhibition.

The Westminster Engineering Co., Ltd. (Victoria Road, Willesden Junction, N.W.), has received a diploma for their projection and photographic arc lamps shown at the Exhibition.

**Agency.**—Andrews and Co., 198A St. Vincent Street, Glasgow, have been appointed representatives of the Midland Electric Manufacturing Co. (Birmingham), whose interests have ceased to be represented by G. C. Fisher and Co.

**Dissolution of Partnership.**—R. Dobson and H. Dobson, Electrical Engineers, 39 Dean Road, Salford, have dissolved partnership.

**Liquidations.**—Engineering Instruments, Ltd., Skerne Works, Darlington, is to be wound up voluntarily, and the business transferred to a new company called the Skerne Works, Ltd. The liquidator is J. W. Watson, Tubwell Row, Darlington.

A meeting of the Beck Flame Lamp, Ltd., will be held at 21 Ironmonger Lane, E.C., on June 30th, at noon, to hear the liquidator's account of the winding up.

Electric Lamp Regenerators, Ltd., is to be wound up voluntarily for the purpose of reconstruction. The liquidator is Mr. F. W. Beard, 480 Salisbury House, London Wall, E.C.

### COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

**Urban Electric Supply Co.**—After meeting interest and debenture stock redemption, the accounts for 1912 show a net profit of £18,496, from which is deducted £10,000 for depreciation, and after paying 3 per cent. on the preference shares, a balance of £996 is carried forward.

**Cleveland and Durham County Electric Power Co.**—A dividend of 3½ per cent. for 1912, carrying forward £148.

**Westinghouse Electric & Manufacturing Co. (U.S.A.).**—The net income of this company for the year to March 31st, 1913, was about £600,000, which is the largest in the company's history. A dividend of 8 per cent. is to be paid on the ordinary stock compared with 6 per cent. in the previous year.

**Edison & Swan United Electric Lighting Co.**—A scheme has been circulated among the 4 per cent. first debenture stock holders and the 5 per cent. second debenture stock holders for the purpose of providing additional working capital, through the absence of which, it is stated, the progress of the company is being retarded. It is proposed to consolidate these stocks into one 4½ per cent. stock, and to call up the outstanding stock as and when required, to an extent not exceeding £1 per share.

## ANNUAL CONVENTION OF THE INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION

**T**HE Incorporated Municipal Electrical Association will hold its Eighteenth Annual Convention from Tuesday to Friday next week, in London and Kingston. The headquarters will be at the Hotel Cecil, and a time-table of the meetings and visits to works will be found in our "Arrangements for the Week" column on

page 330. In accordance with our usual custom we give below portraits and brief biographical notices of the President and the readers of papers, and we also publish descriptions of the features of interest in the works to be visited, which include the Deptford, West Ham, and Lot's Road stations.

MR. C. E. C. SHAWFIELD.

THE PRESIDENT,  
MR. J. E. EDGCOME.

DR. S. Z. DE FERRANTI.

MR. J. CHRISTIE.

MR. W. H. L. WATSON.

MR. R. J. MITCHELL.

MR. A. H. SEABROOK.

### OUR PORTRAITS.

Mr. J. E. EDGCOME was elected President by the Council early this year. He replaces Mr. C. E. C. Shawfield, who was elected President at last year's Harrogate Convention, but has since resigned his post as Chief Electrical Engineer to the Wolverhampton Corporation, and had in consequence to relinquish the Presidentship. Mr. Shawfield will, however, deliver a Presidential address, but a short and possibly less formal address may be expected from Mr. Edgcome. In addition to having been Honorary Treasurer of the Association for many years, Mr. Edgcome has also filled the Presidential chair on a previous occasion, viz., 1905-6. He has been in charge of the Kingston-on-Thames electricity undertaking since 1893, and the latest addition to the works has been two 400-h.p. horizontal Diesel engine sets.

Mr. C. E. C. SHAWFIELD was appointed Chief Assistant

Engineer at Wolverhampton in 1896, and Chief Electrical Engineer in 1898. Very considerable extensions have been carried out recently under Mr. Shawfield's superintendence, in consequence of the increase in the power and tramway loads. Mr. Shawfield resigned his position with the Wolverhampton Corporation last January to take the appointment of Chief Engineer and Joint Manager of the Knowles Oxygen Co., Ltd.

Dr. S. Z. DE FERRANTI'S Paper on "Prime Mover for Electric Power," and the discussion upon it, is looked forward to with the greatest possible interest, following, as it does, so soon after his James Watt lecture, in which, for the first time, he gave a brief description of the turbine on which he has been working for several years. As is known, he considers that it is in the development of the steam turbine rather than in the gas or oil engine that ultimate great improvements in fuel economy are to be sought, and it may be anticipated that the

discussion will be of a technical and controversial nature, and that it will be taken part in by the partisans of the three classes of engines.

Mr. J. CHRISTIE, Chief Electrical Engineer, Brighton, who will contribute a Paper on "Air Filtration," is a past-President of the Association, his year of office terminating with the very successful Convention in Brighton two years ago. He favours the "wet" filter, and will doubtless describe the plant on these lines which has been put in at Brighton to his design.

Mr. W. H. L. WATSON will read a Paper in conjunction with Mr. R. J. MITCHELL on "Electric Vehicles." Mr. Watson is Sales Manager in this country to the sole concessionaires here of the Edison battery, and is making much headway in developing the use of delivery vans. Mr. Mitchell is his assistant, and deals more with the technical side.

Mr. A. H. SEABROOK, Chief Electrical Engineer to the St. Marylebone Borough Council, who will introduce Messrs. Watson & Mitchell's Paper, has taken considerable interest in the question of electric vehicles, and not long ago placed a scheme before his council for a low charging tariff.

### THE DEPTFORD STATION OF THE LONDON ELECTRIC SUPPLY CORPORATION

THOSE who visit the Deptford Generating Station of the London Electric Supply Corporation will find interest from many points of view. Not only is plant still running which was installed in 1889, when Mr. Ferranti startled the engineering world by transmitting energy to London at 10,000 volts, but examples of generating sets and switchgear are to be seen marking the various subsequent stages of development, including the more modern instalments from which power is supplied for the single-phase traction scheme

Davey-Paxman dry back "Economic" boilers. Some of the larger boilers are fitted with the Temperley-Coburn system of steam-extracting pipes, which enables steam generated in the lower tubes to pass freely to the steam space, and this has been found to increase their evaporative capacity. Separately fired superheaters are used on some boilers. Great care is taken to

FIG. 2.—ROTARY STRAINER.

ensure the utmost possible boiler-house economy, and a special laboratory is maintained for fuel, water, and flue-gas analysis. Coal is unloaded from barges by grab cranes and taken to the bunkers by a Temperley transporter.

The lighting section of the engine-room contains a wonderful assortment of 10,000-volt single-phase alternators, including some of the original 10,000-volt Ferranti disc type machines driven

FIG. 1.—GENERAL VIEW OF ENGINE ROOM FROM NEW SWITCHBOARD GALLERY.

of the London Brighton & South Coast Railway, including steam turbine units of 10,000 h.p.

Interesting as it is to look back upon the old pioneering days, it is perhaps not necessary here to recount the whole history of the station. Started in 1889, it was the first station to generate and distribute extra high-tension alternating current. It was equipped originally with some 400-h.p. 2,500-volt sets from the old Grosvenor Gallery station, and the two 1,500-h.p. 10,000-volt machines, which are still at work. The much-talked-of 10,000-h.p. machines put in hand in the early 'nineties were never completed, but in this connection it is interesting to think that the recent extensions have involved turbines of this power. As at present arranged the station gives four distinct classes of supply: the original 85-cycle 10,000-volt single-phase lighting supply, a three-wire 2×230-volt D.C. supply for power and lighting, a three-phase 25-cycle 6,600-volt supply for large power consumers, and the 6,600-volt 25-cycle single-phase traction supply for the Brighton Railway. Generally speaking, the engine-room is divided into two parts, one for lighting and the other for power and traction. Both are served from one common boiler-house containing 24 Babcock & Wilcox boilers and 10

by various classes of engines, besides two B.T.-H. 10,000-volt alternators of more modern type. This generating plant is further supplemented by a 1,500-kw. Westinghouse 10,000-volt motor generator, which takes current from the traction side of the station. Even more interesting than the generating plant in the old part of the station is the original air-break 10,000-volt switchgear designed by Mr. Partridge, the company's Chief Engineer and Manager over 18 years ago, with 4 ft. 6 in. break, which is still in use. Mention should also be made of the special mains charging transformer used to avoid resonance effects, which is in daily use.

The next group of plant, dating from 1904, was installed for giving a temporary supply to the L.C.C. Tramways pending the completion of the Greenwich power-house. This consisted of two 2,000-kw. 6,000-volt 25-cycle Dick, Kerr alternators driven by Ferranti engines, and marks the entry of three-phase plant into the station. For a time these machines ran in parallel with the L.C.C. power-house at Greenwich. A general view of the engine room is given in Fig. 1.

When the company undertook to give a single-phase traction supply to the Brighton Railway, two more Dick, Kerr alternators driven by Ferranti engines were installed. Each of these sets is

capable of giving 2,000-kw. single-phase or 2,500-kw. three-phase, and they are of specially substantial construction. The engines are fitted with Chorlton Whitehead governors. Condensing water is taken from the river and a special form of rotary strainer is used, designed by the engineers of the Corporation.

These strainers were made in the Corporation's own workshops, and were the outcome of a great number of experiments by the Corporation. They have given very satisfactory results, and can, moreover, be installed at an initial cost of about one-third of that of other strainers on the market. The strainer which is illustrated in Fig. 2 consists of a drum perforated with numerous holes, which rotates at about two or three r.p.m. in a cast-iron chamber. It is driven from the centrifugal pump shaft through reduction gear. Any leaves, straw, or other debris entering with the water adhere to the outside of the drum, and are removed by a fixed scraper, the position of which is seen in the figure. This is adjusted so as to have a "shaving" action on the drum surface, so that any solid matter may also be effectively removed, and it all gravitates through a duct at the back of the scraper into the lower part of the housing chamber, which acts as a settling chamber. From this, it is returned to the river through a sludge valve, connected to the return pipe from the condensers, and opened either automatically or by hand.

To meet further extensions in the single-phase traction on the suburban lines of the Brighton Railway, and also in the general power load of the station, a pair of 10,000-h.p. turbo-generators were installed about a year ago. The turbines are of the impulse-reaction type made by C. A. Parsons & Co., Ltd., and

to the large reactance coil kept permanently in circuit to limit the current on short circuit to 10,000 amperes. The whole of the voltage regulation is done by a Tirrill regulator with very satisfactory results. This regulator can be arranged to be cut out whenever a feeder overload relay acts to allow the pressure to drop on short circuit. The railway feeders are all arranged in duplicate. One feeder has an instantaneous trip and the other a time lag, so as to prevent the supply being cut off at the generating station at times of short circuit, the reactance coil and the feeders with the time lag being left in circuit.

Some further generating plant is being installed, but is not yet sufficiently advanced for a description to be included here. There is also a certain amount of sub-station connecting plant in the station for giving a D.C. supply to the immediate neighbourhood.

In spite of the use of plant which has been in service for over twenty years, this company has the lowest cost per unit sold of any company in London.

## THE WEST HAM ELECTRICITY WORKS

THE Electricity Supply Department of the Corporation of West Ham has often been pointed to as an example of one of the most progressive municipal undertakings, and its rapid development is interesting as being largely the result of the specially organised sales and publicity departments initiated by Mr. A. H. Seabrook and ably carried on by his successor, Mr. H. H. Couzens, and by Mr. J. W. Beauchamp, who is now Engineer and Manager. It is not now, however, our purpose to describe the commercial side of the undertaking, which has been dealt with on various occasions in our columns (see *ELECTRICAL ENGINEERING*, March 14th, 1912, p. 129), but to give some details of the generating station and the extensions necessitated by the continually rising load, which were designed by Mr. Couzens and are now being carried out. Among these, members visiting the station on Tuesday will find the new coal-handling plant, the suction ash plant, and the new water circulation system of special interest.

The station is situated at Canning Town in close proximity to the River Lea, and, roughly speaking, consists of parallel engine and boiler houses running at right angles to the river with the remodelled coal-handling plant at the river end, and the extensions where the new plant is being installed at the far end. In the older part of the boiler house we find 20 land-type Babcock & Wilcox water-tube boilers, with an aggregate evaporative capacity of 310,000 lb. per hour, with superheaters and chain-grate stokers, and a larger marine-type boiler for 37,000 lb. per hour by the same makers. Two further boilers of the same size and type are now being erected in the new part of the boiler house. Induced draught produced by steam-driven Sirocco fans is used for the old boiler plant, but the ejector draught system with one short steel chimney to each pair of boilers will be adopted in the extensions. In this case the fans will be electrically driven. The coal-conveying plant is being largely extended and remodelled, and will have a capacity of 60 tons per hour. The new equipment consists of an elevated gantry electric 4-ton jib crane by Carrick & Co. (Edinburgh), and an overhead telfer track running the length of the coal bunker, through the old to the new boiler house, and arranged to work in conjunction with the existing Temperley transporter if required. All this apparatus is driven by 550-volt D.C. motors, which take their current from the live side of the circuit-breakers controlling the traction supply. The coal collected by the crane from the barges is deposited either in the 3,000-ton reinforced concrete storage bunker on the wharf either direct or through the weighing machine on a travelling gantry over the store, or it can be fed, weighed or unweighed direct to the telfer machine. A view of the river end of the station, showing part of the coal-handling plant, is given in Fig. 1. The overhead bunker running along the centre of the old boiler house terminates in a two-way bunker and screw-conveyor capable of conveying coal from the old bunker line to the new bunkers.

An interesting feature of the station is the suction ash-collecting plant, which was installed by Babcock & Wilcox, Ltd. The general principle of this is shown in Fig. 5. A system of cast-iron pipes (B) runs along the ash tunnels, provided with removable covers beneath each ash discharge, and open at the far end. The other end leads to the top of the receiver C, which is capable of holding about six tons. A suction pipe E leads to the exhauster F, which is driven by a 50-h.p. motor, and the powerful suction produced causes all the ash placed in the pipe to be carried over into the receiver, which continues to fill up until its weight opens the cut-off valve D against

FIG. 3.—ENCLOSED ISOLATING SWITCHES.

are coupled to 7,500-kw. three-phase alternators made by Brown, Boveri & Co. These machines are self-ventilating and draw specially filtered air from ducts below. For this purpose a special air-washing plant has been installed for one of these plants by the Sturtevant Engineering Co., capable of dealing with 30,000 cu. ft. of air per minute.

These air filters are contained in a steel casing provided with two glazed inspection doors and with a tank at the base. The air entering this casing immediately comes into contact with a fine mist produced by a number of special spray nozzles, any impurities in the air falling with the water into the catch tank. The air then passes through a series of eliminator plates, which arrest any free or entrained moisture. The spray nozzles are supplied with water at the required pressure by a small motor-driven centrifugal pump, provided with a pot strainer in the delivery pipe. The tank is fitted with a ball-cock to make up any losses of water, and large drain and inlet pipes to admit of the tank being emptied and filled rapidly when it is necessary to change the water. The arrangement has several advantages over the cloth screen type of filter.

Like the reciprocating sets, the turbo-alternators can be used for single-phase or three-phase supply, and the specially arranged switches, which enable them to be put either on the three-phase power bars or the single-phase power bars, form one of the points of interest in the switchboard. The board was specially constructed by the British Thomson-Houston Co. to the design of the London Electric Supply Corporation, and among its special features may be mentioned the enclosure of the isolating switches in earth shields, with the current transformers also clamped outside the earthed covering. The general arrangement of these isolating switches is seen in Fig. 3. The main oil switches are of the B.T.H. Co.'s standard motor-operated pattern, and have been proved by tests to be capable of breaking enormous short-circuit currents. Attention should also be drawn

the air pressure, and the contents of the receiver are discharged. A travelling electrically-driven crusher, A, is provided to deal with hard clinker, but this has only been used on rare occasions. The suction pipe is of cast-iron, and all bends are fitted

were commenced consisted of two 1,200-kw. Bruce Peebles and two 600-kw. G.E.C. two-phase 2,000-volt alternators, and three 500-kw. Bruce Peebles D.C. 500-volt traction sets, all driven by Ferranti engines, and the more recently installed steam turbine

FIG. 1.—GENERAL VIEW OF WEST HAM ELECTRICITY WORKS, SHOWING OLD AND NEW COAL-HANDLING PLANT.

with removable pieces, which may be easily replaced in case of wear. A spray pipe is provided at the top of the receiver to quench the ashes. (Some further details of this apparatus were given in *ELECTRICAL ENGINEERING*, July 25th, 1912, page

plant, consisting of two 1,500-kw. two-phase Willans-Dick, Kerr turbo-alternators, one for 2,000 and the other for 6,000 volts, and two 3,000-kw., two-phase, 6,000-volt Westinghouse turbo-alternators. The way in which the turbo-generators were fitted

FIG. 2.—BOTTOM HALF OF CASING OF 5,000-kw. TURBINE WITH ROTOR IN PLACE.

421.) It may be mentioned here that the make-up feed water is provided by an artesian well, and that an Archbutt-Deeley water-softening plant is in use.

The generating plant in the engine-room before the extensions

in between the reciprocating sets practically without adding to the floor space required is worthy of note. A pair of 500-kw. G.E.C. synchronous motor-generators act as the connecting link between the A.C. and the D.C. plant, and a group of trans-

formers placed in cells open to the air outside the main wall connect the 2,000- and 6,000-volt systems. The new generating plant now under erection in the extension to the engine-room consists of a 5,000-kw. Willans-Siemens 6,000-volt two-phase turbo-alternator running at 1,500 r.p.m. This turbine, which is shown under erection in Fig. 3, is of the combined impulse and reaction or "disc and drum" type, with a single impulse wheel and 27 rows of reaction blading. The generator will be ventilated by a motor-driven fan forcing air into the machine through a cloth filter. An overload capacity of 25 per cent. for three hours, and 50 per cent. for one hour, is guaranteed. The condensing plant for this set has Edwards air pumps and a live steam jet vacuum augmentor. There is space in the extended engine-room for at least two more 5,000-kw. sets.

The circulating water arrangements are undergoing considerable modification. Condensing water is taken from the River Lea. According to the original scheme, this water supply is not available at times of low tide, when a series of cooling ponds are made use of adjoining the station which formerly were part of a sewage treatment scheme. When the new water system is complete, however, water will be obtainable at all states of the tide, and the use of these cooling ponds will be discontinued. The new system involves a 36-in. suction pipe to the pump house, a delivery line of the same size along the engine room, and a 48-in. return, with branches and valves to allow the water to be returned either above or below the suction inlet, according to the direction of the tidal flow in the river. The equipment is large enough to deal with all the future plant for which the building extensions are designed, and the three electrically-driven Rees Roturbo pumps will have each a capacity of 70,000 gallons per hour. Only two of these, however, are now installed. The same form of rotary strainer

FIG. 3.—SUCTION ASH PLANT.

is used as at the Deptford station of the London Electric Supply Corporation, illustrated and described on another page of this issue.

The new switchgear, all of which was supplied by the British Thomson-Houston Co., is placed in a separate room parallel to the engine-room, and operated by solenoid remote control from a gallery along the side of the engine-room. The present capacity of the board is the control of three 5,000-kw. generators and nine 3,000-kw. feeders. The oil break switches are capable of opening circuits with a load of 20,000 kw., and have a stroke of 7 in. with two breaks per phase, under a head of 9½ in. of oil, and air buffer space of 9 in. The generator switches are provided with reverse tripping devices of the balanced type, unaffected by excess of current or potential, and fitted with air dampers for synchronising. In addition, maximum overload relays are provided, fitted with fuse-pattern time-limits. The feeder switches are also provided with fuse-pattern time-limits, having inverse time characteristics. An interconnector panel capable of carrying 10,000 kw. forms the link with the old board. The voltage is controlled by a Tirrill regulator, and surge arresters of the electrolytic type are installed.

The bulk of the supply from the station is at 6,000 volts, two-phase, at which pressure it is supplied throughout the dock and Silvertown districts and to the more important industrial district in the north. From the 6,000-volt mains an extensive system of 2,000-volt subfeeders radiates. At this pressure a very considerable number of moderate-sized works are supplied. The two-phase mains are in the form of twin-concentric lead-covered cables, and practically the whole of the cable system consists of British Insulated and Helsby material

drawn into stoneware ducts. The general low-tension supply is at 200 and 100 volts, single or two-phase, whilst the traction is partly furnished at 550 volts D.C. direct from the generating station, and partly through the medium of rotary converters off the 6,000-volt A.C. system.

At one of the sub-stations in Bridge Terrace an 800-kw. rotary converter has recently been installed by the British Westinghouse Co., which has several points of interest. It is a six-phase machine running at 600 r.p.m., and is fitted with a starting motor and a booster, direct coupled at opposite ends. Starting is arranged for either from the A.C. side by means of the starting motor, in which case synchronising is performed on the E.H.T. side of the transformers, or from the D.C. side by means of a starting switch and starting resistance. The rotary converts from a two-phase 50-period supply, of which the voltage may vary from 5,750 to 6,600 to continuous current at a voltage between 500 and 550. It is provided with an A.C. synchronous booster, which enables the attendant to obtain complete and independent control over the power factor, and the voltage on the continuous-current side. Thus a power-factor of unity or a leading power-factor may be maintained at any continuous-current voltage between the above-mentioned limits and with any A.C. voltage between 5,750 and 6,600. As a matter of fact, under the conditions which exist at West Ham, the machine runs invariably at full load with a leading power-factor of 90 per cent. By this means the lagging currents taken by other induction plant on the system are neutralised, with the result that the average power-factor over the whole of the system is considerably improved. This rectification of power-factor is, of course, an inherent property of the rotary converter, and, together with the high efficiency of this class of machine, constitutes an important advantage in favour of this type of converting plant.

The machine runs quite sparklessly on all loads up to 25 per cent. overload, which overload it is capable of withstanding for 24 hours. An interesting feature is the "mechanical oscillator" attached to one end of the shaft. Its function is to give a periodic oscillatory motion to the rotating part of the machine, in this manner effectually preventing the corrugating of the commutator and slip-rings, and thus giving the best possible commutating conditions. This is accomplished by a cam on the surface of which a ball rolls bearing against the end of the shaft. The continuous-current brushgear is of a novel design of a radial telescope type, which ensures a maximum distance between adjacent brushes, and practically eliminates the possibility of the machine flashing over when subjected to short circuits.

In conclusion, we wish to express our thanks to Mr. J. W. Beauchamp for his courtesy on the occasion of our representative's visit to the station, and for putting illustrations and descriptive details at our disposal.

## THE POWER HOUSE OF THE LONDON ELECTRIC RAILWAYS AT LOTS ROAD

THE famous Lots Road power house, supplying the greater part of London's underground railways, which will be visited on Wednesday afternoon, has the distinction of being the largest generating station in this country in point of output, although for its plant capacity it is compact even in its vastness. This is partly accounted for by the double-decked boiler-house, which, we believe, is the only one of its kind on this side of the Atlantic. With its present plant-capacity of 48,000 kw., the annual output exceeds 150 million units, and the peak-load is about 42,000 kw. The station is not inter-connected with any other, and supplies the whole of the District, Baker Street and Waterloo, Great Northern and Piccadilly, Charing Cross, Euston and Hampstead, and East London Railways, and part of the London, Tilbury and Southend Railway, as well as the Kingston section of the London United Tramways. A supply of power is also given to the London, Tilbury and Southend Co.'s workshops, and there is a scheme for giving a bulk supply to Richmond. Plant extensions will possibly be added before long, but no definite decision has been made as to the form they will take.

The site comprises 3½ acres, with a water frontage on the Thames and on Chelsea Creek of 1,100 ft., and a road frontage of 824 ft. The actual dimensions of the main building, consisting of boiler-house and engine-room running parallel, are 453 x 175 ft., not including the office block. The building itself is of steel enclosed with brick and terra-cotta, and the four chimney shafts (built by the Alphons Custodis Co.) are 19 ft. internal diameter and 275 ft. high. Coal can be obtained either by rail or river, and a remarkably fine coal-conveying

plant is at work. 400 or 500 tons of coal are consumed per day, and the bunkers themselves can accommodate some 15,000 tons. An additional cylindrical steel-lined pit or tank is now nearly completed, where a further 17,000 tons will be stored under water as a special reserve in case of strikes, &c. A special ash-handling plant is provided in a separate building, from which ashes are removed by those purchasing them as a by-product. This is served by a storage battery locomotive and pneumatic hoist, and in this connection it may be remarked that compressed-air power is employed for capstans, barge basin-gate mechanism, as well as for large condenser valves, &c., within the power-house. The boilers are of the well-known Babcock and Wilcox land type, 64 in number, arranged, as already stated, in two stories, and carried directly by the steel frame of the building. Floor space is available for 16 further boilers. Each has 5,212 ft. of heating surface, and they are arranged in groups of eight, each belonging to one generating set, but there is also steam connection between the groups. Chain-grate stokers and economisers are provided, and each boiler has its integral superheater.

A general view of the turbine-room is shown in the accompanying figure. There are eight main turbo-generators, besides an auxiliary set, and the separate steam-driven exciters, and there is floor space for two more large sets. The main generators are driven by horizontal pure-reaction type turbines made by C. A. Parsons and Co. (Newcastle-on-Tyne), running at 1,000 r.p.m. These are constructed in two cylinders arranged so that the flow of steam is in opposite directions. The governing on

in the foreground of the figure. They are four in number, each for 125 kw. at 125 volts. The exciter bus-bars can also be fed from storage batteries, of which there are two of 5,000 ampere hours' capacity, each capable of maintaining the full excitation for six hours. The travelling-crane motors, the oil-switch motors, and a part of the station lighting are also supplied from this circuit. All other auxiliary motors within the station are driven by three-phase, 220-volt motors. For this purpose, 220-volt, three-phase bus-bars for the auxiliaries are run high up on the turbine-room wall on the opposite side to the main switchgear, and these can be fed from one end by a separate 1,500-kw. Parsons turbo-generator set or from the other end by a bank of transformers off the main supply. Arrangements are also being made for the installation of transformers which will be able to be connected to each alternator, so that if desired each set can run its own auxiliaries independent of the rest of the station.

It now only remains to describe the switchgear and outgoing feeder system. The switchgear is carried on three gallery floors, which can be seen in the figure, and the whole equipment was supplied by the British Thomson-Houston Co., Ltd. (Rugby). The machine cables are taken vertically up to the generator oil switches on the first floor, which stand (as shown in the figure) well away from the compartments for the feeders coming down from above. Like all the other oil switches, they are of the B.T.H. Co.'s standard remote control, motor-operated pattern, and are of ample size to deal with the enormous currents which they might have to open on short-

GENERAL VIEW OF TURBINE ROOM AT LOTS ROAD, SHOWING PARSONS-WESTINGHOUSE TURBO-GENERATORS, EXCITER SETS IN FOREGROUND AND SWITCHGEAR GALLERIES IN BACKGROUND.

normal loads is by varying the continuity of the steam admission, but a second governor acts on a bye-pass when overloads are called for. They take steam at about 120° superheat, and are extremely efficient as regards steam consumption. The generators are of the British Westinghouse Co.'s manufacture. They have been somewhat altered since they were originally installed, with a view mainly to increasing their output, which is now 6,000 kw. at 11,000 volts, 33½ cycles, three-phase normal rating, and 50 per cent. overload for 2 hours. The increase in output over the original rating of 5,500 kw. was obtained principally by enclosing the machines and rendering them self-ventilating by drawing air from ducts below. The rotor itself forms the fan, so that no separate ventilating plant is required, nor are there any very elaborate air-cleaning plant. The condensing system consists of vertical condensers, each with 15,000 sq. ft. of cooling surface; these are located in pits between the engine foundations. The circulating water is supplied by 66-in. pipes laid to the edge of the channel of the Thames. Each condenser has a 20-in. centrifugal pump; the duty of the pump is simply to overcome the friction of the pipes, as the system is arranged on the syphonic principle, the top of the condensers being within 29 ft. of minimum low tide, and the circuit is closed. The intake and discharge mains are arranged for reversible flow, and the water passes through a revolving screen of novel design. The condensers are designed to work on the dry-vacuum principle, the air pump and the water pump being separate. A very complete oil-cooling and filtering plant is installed, and the size of this gives a good idea of the large scale on which everything is carried out.

The exciters are driven by the reciprocating engines shown

circuit. The second gallery contains the main bus-bars in separate compartments, one above the other, and divided into five sections coupled by oil switches of heavy breaking capacity. The third gallery contains the feeder bus-bars, which are divided into ten sections in a similar way, and each section is connected by an oil switch to the generator bus-bars immediately below. From these bars are taken 65 outgoing feeders. The duplicate feeders supplying the same sub-station are kept as far away from each other on the board as possible. The control boards are compactly arranged in a projection built out in front of the centre of the second gallery. In front of the operator is the desk-pattern generator control board of 11 panels (including bar-coupling panels), while the instruments for the machine circuits, including wattmeters and power-factor meters, are conveniently mounted just above the line of sight without interrupting the full view of the turbine-room. It may be mentioned here that the load has usually a leading rather than a lagging power factor, as practically the whole of it is to rotary converters. Voltage regulation is entirely by hand, and no automatic regulators of any kind are used. The feeder board of 18 vertical panels, containing the necessary small control switches, indicators, relays, and instruments, is behind the operator. The protective arrangements are as straightforward and free from complication as the rest of the station. The neutrals of the alternators are all kept earthed through a common bar, and a resistance limiting the current to earth to 1,000 amperes, and the current transformers in each phase, are connected between the windings and the neutral point, so that their insulation is not subjected to a high voltage. Plain overload tripping gear set fairly high, and without time-limit

feature, is fitted to each phase of the generator and feeder switches. Reverse-current trips are only used at the sub-station ends of the feeders. Excessive surges are taken care of by aluminium electrolytic arresters, which are found to be more reliable than spark-gaps. The auxiliaries are controlled from a separate board at one end of the turbine-room. A line of 64 ducts carries the feeders to the nearest point on the District Railway at Earl's Court, from which cables follow the railway routes to the various sub-stations.

### PUMPING PLANT AT THE NEW CHINGFORD RESERVOIR

**T**HE principal engineering interest at the King George's reservoir of the Metropolitan Water Board at Chingford is the installation of "Humphrey" gas pumps.

There are five of these pumps, four of which are capable of delivering 40 million gallons each, and one 20 million gallons per day. The pumps themselves were manufactured at the works of the Siemens Brothers Dynamo Works, Ltd., Stafford, to the designs of Mr. H. A. Humphrey, of the Pump and Power Co. (38 Victoria Street, S.W.). The general principle of the Humphrey pump is the use of a combustion chamber similar in function to the cylinder of a gas engine, but with the column of water to be pumped acting as the piston in direct contact with the exploding gas. There are thus no moving parts except the gas inlet and exhaust valves and the water inlet valves. Following the cycle of operations, the first explosion of a compressed charge puts the column of water in the U-shaped delivery pipe in motion, and gives it a momentum which carries it far beyond a point where the expansion of the gases is complete, and thus draws in more water through the inlet. Surging back, the water sweeps out the products of combustion, shuts the exhaust valve by its impact, and imprisons and compresses a certain quantity of the products of combustion in a pocket under the gas inlet valve, surging out again, it sucks in a fresh charge, and on the next rush inward compresses the charge ready for the next explosion. Thus the whole action depends on the swing of the body of water in the delivery pipe, which plays the part both of piston and flywheel. The inlet and exhaust valves are interlocked in an ingenious manner, whereby when the inlet opens and closes, it locks itself shut, and releases the exhaust valve, which in its turn, after opening and closing, locks itself and releases the inlet. The ignition is timed by an appliance resembling an indicator so that it occurs at the moment of maximum compression pressure. The pump is started by a stroke with compressed air followed by a sudden opening of the exhaust valve, thus initiating the oscillation of the water column which is afterwards continued automatically.

**The Illuminating Engineering Society.**—The annual report records a present total membership of over 400, of whom 35 are electrical engineers, 19 are connected with the gas industry, and the remainder interested in other ways in lighting generally. Seven meetings have been held during the past session, in addition to the annual dinner, and the committees on school and library lighting have continued their labours. There has been increased co-operation with kindred institutions, particularly in America and Germany, and the society has been represented at various congresses. Reference is made in the report to the Home Office Departmental Committee on industrial illumination and activity in other countries in the direction of securing improved lighting in factories, &c.

**Electrical Trade with China.**—It has sometimes been said that British electrical manufacturers are not receiving their share of the business that is to be had. In contradiction to these remarks, it is a pleasure to be informed by one of the largest firms in this field in China that their experience has been different. We hear, however, from the General Electric Co. that the General Electric Co. of China, Ltd., which was formed in 1911, have recently secured several contracts for the supply of electrical machinery for Chinese cities of Soochow and Changchow in Kiangsu Province. All this plant will be manufactured at the Witton Works of The General Electric Co., Ltd., in England. For Soochow, a Witton single-phase alternator capacity 375 kw. with high-tension switchboard is being supplied as an extension of the present generating plant. In the case of Changchow, which is a similar city, a Chinese company has been formed, and the contract secured for a Witton alternator about 200 kw. complete, with high-tension switchboard, Allen's engines, &c. Another contract recently secured has been for three Witton high-tension alternators with 14 panel switchboard for the lighting of Fatchan in Kwangting Province. We have received an interesting photograph showing the members of the staff (both Eastern and Western) of the G.E.C. Chinese house. The headquarters are at Shanghai, and sub-branches are located at Hongkong, Tientsin, and other places.

### THE I.M.E.A. BILL

**O**NCE more has the Incorporated Municipal Electrical Association brought forward its Bill to amend the Electric Lighting Acts. Sir William Howell Davies, M.P. for South Bristol, introduced the measure last week, and it was read a first time; the second reading of the measure is down for July 8th.

The Bill is almost identical with that introduced last year.

Clause 1 provides that any local authority authorised by Act of Parliament or Provisional Order to supply electricity "may provide, sell, let for hire, and fix, repair, maintain, and remove, but shall not manufacture for the purpose of sale or letting on hire electric lines, fittings, apparatus and appliances for lighting, heating and motive power, and for all other purposes for which electrical energy can or may be used, and may provide all material and work necessary or proper in that behalf. . . ." The charges in respect of this portion of a local authority's undertaking have to be adjusted so that they meet the expenditure, including capital charges; separate accounts have to be rendered to the consumers, and a separate account must be included in the annual accounts of the undertaking.

Under Clause 2 powers to provide electrical fittings, &c., are conferred upon companies.

Clause 3 authorises all electric supply undertakers to provide and maintain showrooms, to hold exhibitions, and generally to advertise the undertaking.

Clause 4 appears for the first time, and authorises electric supply undertakers to sell bye-products.

Clause 5 is the usual stand-by supply clause.

Clause 6 provides for the payment out of revenue of subscriptions and delegates' expenses in connection with associations dealing with the supply of electricity, provided that the number of delegates at any meeting does not exceed four.

Under Clause 7 a local authority is empowered to utilise its net profits for the formation of a fund for working capital, which, however, must not exceed one-half of the gross revenue of the undertaking for the time being.

Clause 8 authorises the borrowing for the purposes of working capital sums not exceeding one-tenth the amount expended upon the purchase of lands and the constructions of works prior to the expiration of three complete years from the commencement of the undertaking, or one-tenth of the amount which the undertaker has been authorised to borrow for the purposes of the undertaking prior to the expiration of that period, whichever amount is the larger. Any money borrowed under this section, however, is to be repaid within ten years from the date of borrowing, but the undertaker may postpone the commencement of repayment until two years from the date of borrowing.

The provisions of the Conspiracy and Protection of Property Act, 1875, are extended to electricity undertakings under Clause 9. They at present apply to gas and water works, and are intended to provide against strikes of workmen without proper notice.

Clause 10 provides against obstruction to officers of undertakers entering upon premises for meter reading or removal of fittings.

Clause 11 authorises the laying of cables in streets not dedicated to public use, at the request of the occupier of any premises therein. At present electric supply and similar undertakers have only rights to lay mains in public streets and not private thoroughfares.

Clause 12 empowers a number of electric supply undertakers to carry out jointly the provisions of Clauses 1, 2, and 3.

As will be seen the much-discussed wiring clause is again in the Bill, but apart from that, practically all the other provisions are non-contentious, and the passing of the Bill would undoubtedly facilitate the working of electric supply undertakings generally throughout the country, and obviate the necessity for separate applications to Parliament for these powers in private Bills. The promoters had hoped that the Institution of Electrical Engineers and the British Electrical and Allied Manufacturers' Association would have seen their way to give the Bill their official support. It is believed that many influential members of both Institutions feel that the passing of the Bill would be for the ultimate good of the industry, but owing to the absence of unanimity they have been reluctant to press their opinions. The point to be remembered is that the powers asked for in the Bill are already possessed by gas undertakings, which are thus able to make competition with electricity so much the more effective.

**The Electrical Trades Benevolent Institution.**—A promise of £100 from Mr. Justus Eck, who has just returned from a Colonial tour, has been received in connection with Mr. Byng's offer. There now remains £400 more to be promised to fulfil the conditions of Mr. Byng's original gift. It may be remarked that so far all the donations have been from individuals, and not from firms.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS :** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS :** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,342.

What is the greatest error commonly met with when using single-phase dynamometer-type indicating wattmeters on power-factors down to 0.3 with frequencies varying from 15 to 100 cycles per second? The instruments consist of a single moving coil for the pressure circuit, and two fixed coils for the current circuit, no iron being used.—"Vivo."

(Replies must be received not later than first post June 19th.)

### ANSWERS TO No. 1,340.

Please show how an ordinary incandescent lamp could be connected to a 25-h.p., 220-volt, compound-wound, D.C. motor circuit, to act as a signal at a distant point, in the event of the motor ceasing to run by any cause.—"SIGNAL."

The first award (10s.) is made to "PHIZ" for the following reply:—

If approximately normal voltage exists between the brushes of a D.C. motor, the machine must necessarily be running, since otherwise the rush of current through the armature would be so great as to blow the fuses or trip the overload release, thus cutting off the supply from the motor. It is therefore only necessary to connect the lamp so as to indicate whether any voltage exists between the brushes of the motor. The best way to do this is to make the connection to the terminal board of the motor itself in such a way that the lamp is in parallel with the armature, as shown in Fig. 1. So long as the motor is running, the lamp will burn, but if the motor is stopped

either by opening the main switch or the starting rheostat, or by the blowing of a fuse or the failure of supply, the lamp will be extinguished. In the event of an open circuit occurring on the shunt field, the motor will "run away," and immediately the overload device operates and stops the motor, the lamp will go out. It is therefore impossible for the lamp to be lit when the motor is not running, unless an open circuit exists in the series circuit of the motor itself. This might occur due to one of the following causes: (1) A "burn out" of the armature or a connection. This, however, would undoubtedly operate the overload release, stopping the motor and extinguishing the lamp. (2) If the brushes had been raised from the commutator for any reason, and not replaced, on attempting

to start up, the lamp would light, but the motor would not start. This would presumably be immediately noticed by whoever was attempting to start the motor. (3) It is conceivable that an internal connection might fail, due to the slacking off of a terminal nut. If this occurred anywhere between the terminals to which the lamp is connected, the motor would, of course, stop, and the lamp would remain alight (unless the connection fell in such a way as to cause a short circuit and operate the overload release). This is a somewhat unlikely contingency, but if it is desired to provide against the possibility, it could be done by making the lamp connections to the two "bus rings," which carry the current to the brush studs, instead of to the terminals of the machine. A tumbler switch should be inserted in the connections for the purpose of switching off the lamp while the motor is running, if this is desirable for any reason, and, of course, fuses will be necessary for the protection of the lamp circuit. If it is desired that the lamp shall be normally dark, but shall light up when the motor stops it will be necessary to use some form of relay on the lines shown in Fig. 2. The relay is connected across the terminals of the motor, instead of the lamp, and so long as the relay is energised, the switch S will be held open. Immediately the voltage on the relay coil falls below, say, half the normal voltage, the relay armature will fall and close the switch S, thus lighting the lamp. The advantages of this arrangement are that the lighting of the lamp is more likely to attract attention than its going out; also that it is possible to connect a bell in parallel with the lamp, as shown, to call immediate attention to the fact that the motor has stopped. The disadvantage lies in the increased complication and the fact that the normal condition of the lamp is unlighted. In the event of a mishap to the lamp circuit, such as the breakage of a filament or a failure of supply, the lamp would not indicate anything wrong, although in the latter case the motor would be stopped if it was dependent on the same supply. If the lamp is normally alight, as is the case with the connections shown in Fig. 1, a failure of the lamp circuit would extinguish the light and thus lead to a prompt investigation of the trouble.

The second award (5s.) is made to "E. H.," who writes as follows:—

There are three possible causes for a motor ceasing to run: (1) failure of the supply voltage, (2) an overload bringing the starter to the "off" position, and (3) a break in the electrical circuit at any other point except in the shunt, in which case the motor would speed up depending upon the nature of the load and the amount of series winding on the field. To indicate the stoppage of the motor, an incandescent lamp can be employed in two ways, either (1) to burn only when the motor is running, or (2) to light up when the motor stops. The latter alternative would be preferable, but it entails a much more complicated apparatus, since a second independent supply would be necessary, otherwise the lamp would not indicate the stoppage of the motor due to the first cause mentioned above. Hence we fall back upon the first method, and the simplest way to obtain the desired signal is to connect the lamp across the armature. It is well known that the speed varies as back E.M.F. of armature conductors in series  $\times$  flux

so that when the voltage falls to zero, the motor ceases to run, and the lamp is extinguished. The possibility of a break in the armature connections stopping the motor but leaving the lamp alight is exceedingly remote, since there are at least two paths in parallel through the armature. Another but more expensive method would be to couple a tiny shunt dynamo either directly or by belt to the motor, and connecting the lamp across its terminals.

Among the very numerous replies received there is general agreement that the simple connection of a lamp to light up when the motor is receiving its supply is the most satisfactory method. Many competitors, however, describe methods of carrying a lamp to light up when the motor stops, in some cases by means of a relay, and in some cases by contacts carried by the starter arm, but by no means all have realised that an independent supply is necessary for the lamp in this case. Others prefer centrifugal switches or similar devices varying in complexity, controlled by the actual rotation of the motor spindle.

**The Ghent Exhibition.**—A fine exhibit is being made by the Great Central Railway at the Ghent Exhibition. Among the special features is a scale model of the new Immingham Dock, 26 by 15 ft. in area, a locomotive boiler fitted with the Robinson superheater, and illustrations of the Great Central latest Sir Sam Fay express engine.

LONDON

## ELECTRIC FANS

APPROPRIATELY to the time of year, The General Electric Co., Ltd. (67 Queen Victoria Street, E.C.), have sent us some particulars of the large business which they are doing in their electric "Freezor" fans. This branch of their work is the subject of a special advertising campaign, in which they invite the co-operation of contractors. We have already given a full description of the extension to the Wotton Works which were built for the production of these fans (see *ELECTRICAL ENGINEERING*, June 13, 1912) and here small motors from 1/80 to 2 h.p. for continuous and for alternating current for all purposes are also made and very thoroughly tested before being sent out. The design of the motors and blades is such that the light weight pattern of 12-in. desk fan consumes no more than 25 watts. The patterns made include ceiling fans, oscillating fans, and revolving fans, as well as exhaust fans and punkahs of various designs for tropical countries. The Company have organised a system of express delivery which obviates the necessity for contractors to carry large stocks of fans, and they are co-operating with the trade to create a demand for fans by the preparation and issue of suitable literature.

## ELECTRIC TRACTION NOTES

Two important orders for electric trains have been placed. The London and South-Western Railway has ordered 84 motor trains (each having two 2-motor motor cars), from the British Westinghouse Co.—an order of about £280,000 in value. Particulars of the electrical equipment of the line appeared in our issue of December 12th, 1912 (p. 696). The London and North-Western Railway has ordered 40 trains, for the lines they are equipping electrically, from the Maschinenfabrik Oerlikon, a large Swiss firm, with works near Zurich, which town is, by the way, not in Germany, as is announced in a contemporary.

The Manchester tramway accounts for the past year show a net balance of £196,851, of which £100,000 is allocated to relief of rates and the balance to reserve. The number of passengers carried was 187,675,183, compared with 174,424,237 in the previous twelve months, and the total average working expenditure was 7'182d. per car mile.

The Brighton Corporation has adopted the recommendation to run trolley 'buses from North Street to Preston, over a two mile route. The initial cost is £5,600, and double-decked trolley 'buses are to be used.

Of the £6,000 profits from the South Shields tramways last year, a sum of £1,600 is to be transferred to relief of rates.

The working of the G. B. surface-contact system at Lincoln for 1912-13, again shows satisfactory results, the total expenses per car mile run being 6d., compared with 6'05d. in the previous twelve months, and 6'22d. for the Lorrain system of Wolverhampton for 1912. Compared with the average working costs of 79 other municipal tramways operating on the overhead system for 1912, the Lincoln figure is 6d. against 6'54d.

Mr. T. B. Goodyer, General Manager of the Croydon Corporation Tramways, calls our attention to the paragraph on page 325 of our issue for the 5th inst., in which it is stated that, with the exception of the L.C.C., the whole of the tramway and motor-bus services in the Metropolitan area are now under one control, and points out that there are a large number of municipal tramway systems in the Metro-

politan area which have not yet been absorbed. What we wished to convey was, that practically all the tube railways, tramways and buses in the County of London, except the L.C.C., are now under the one control.

## TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

A bill has been introduced by the Dutch Government for the laying of a new telephone cable between Holland and Great Britain. The length will be 165 kilometres, and the cost of £62,000 will be equally shared by the British and Dutch postal authorities. Landing places are proposed at Westkapelle (Island of Walcheren) and Orford Ness (Suffolk), and it is anticipated that the cable will be laid by September of this year.

The latest automatic telephone exchange in this country is to be at Newport. It is to be one of 2,000 lines, and of the same type as that in use at Epsom, the "Official Switch," and under erection at Leeds. All of these were supplied by the Automatic Telephone Manufacturing Co., Ltd., who have received the order for Newport.

An International Conference, upon which is represented Great Britain, Germany, France, Belgium, Denmark, Norway, Portugal, Spain, Sweden, and the Netherlands, is meeting in London to consider the measures which should be taken to secure, as far as possible, immunity from damage to cables caused by fishing vessels and anchors of vessels of all descriptions. The meetings are private, and expected to end at the close of this week.

The trial of Mr. Cecil Chesterton at the Old Bailey for criminal libel against Mr. Godfrey Isaacs, managing director of Marconi's Wireless Telegraph Co., ended on Saturday in a verdict of guilty, and a fine of £100 was imposed, together with payment of the costs of the prosecution.

The Ottoman Administration state that the route via Otranto Vallona cannot now be regarded as an Ottoman route. The Meshed line was repaired on 4th inst., and on the 7th the Moroccan Office stated that owing to the insecurity of the region traversed by courier between Arzila and Arbavua there is long delay on telegrams. The Portuguese Government has opened a wireless coast station at Lisbon for general public correspondence. The normal range is 350 kilometres, wave length 600, call signal C.R.F., and the coast rate is 50 centimes per word. On the 9th inst. it was only possible to send telegrams between Tangier and Arzila by wireless. The Jamaica-Colon cable of the West India and Panama Telegraph Company was down in May last, and is not yet repaired. Denmark, Egypt, the United States of North America, Holland, and Russia have ratified the final Protocol of the Radio-telegraphic Convention of London. Holland's adhesion also covers Curacao and the Netherland Indies.

**Cinematograph Regulations.**—The Home Office has amended the regulation only allowing electric light or limelight, and now permits the use of acetylene, provided that certain conditions are observed.

**I.E.E. Students' Section.**—The constitution of the Committee of the Students' Section of the Institution of Electrical Engineers for the session 1913-14 as determined at recent meetings is as follows:—Chairman, Mr. S. M. Hills; Vice-Chairman, Mr. R. E. Dickinson; Hon. Secretary, Mr. E. T. Driver; Hon. Assist. Secretary, Mr. R. A. McMahon. The extra-collegiate members of the Committee are Messrs. P. R. Coursey, E. L. M. Emtage, T. J. Hornblower, G. W. P. Page, J. C. Rennie, and H. K. Whitehorn; while the collegiate representatives appointed are Messrs. R. S. H. Boulding (City and Guilds, Engineering, College), J. G. Deedes (Finsbury Technical College), A. Deimel (King's College), H. Riley (East London College), and P. J. Wheeler (Northampton Institute).

## "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

### Specifications Published June 5th, 1913

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

**11,380/12. Resistors for High Temperatures.** G. COOPER (British Prometheus Co.). The surface is impregnated with a colloidal solution of one or more of the noble metals. To effect this a layer of oxide or other absorbent compound is formed on the surface of the resistor, the coating solution is then applied and subjected to heat and heavy pressure by a suitable machine. Four figures.

**11,388/12. Engine Starter and Lighting System.** W. H. SCOTT (Laurence Scott and Co.). In combination with an electric motor and epicyclic gear are a brake and clutches whereby should backfire occur the brake is released and the housing or disc of the planet wheels of the gear is freed, so that the gear is inoperative. When running the motor is driven as a dynamo, and may be arranged in conjunction with storage cells, so that it effects the lighting of the car. This arrangement was shown at the last Motor Car Exhibition at Olympia (see ELECTRICAL ENGINEERING, Vol. VIII., p. 651, Nov. 21st, 1912). Seven figures.

**11,586/12. Switches.** P. V. HUNTER and W. L. SHAND. The circuit is broken in two points, the contacts being drawn apart so that two arcs are formed close together, with the current in each flowing in opposite directions, so that they repel one another, and are blown out. Six figures.

**11,870/12. A.C. Mercury Vapour Lamps.** E. E. DARMOIS and M. A. E. LEBLANC. An inductance is connected in series with the lamp which has a pair of electrodes for each phase. The supply pressure across the lamp and inductance must not be less than 800 volts at 50 cycles per sec. To start up the lamp is heated and this is made easier by surrounding the tube adjacent to one electrode with a metal conductor connected to the other electrode. To reduce the temperature of the mercury electrodes, iron, nickel, or other metal with a higher conductivity is inserted in the mercury. Eight figures.

**12,270/12. Starting Mercury Vapour Lamps.** P. G. TRIQUET. To effect lighting by rotation of the lamp around the axis of the tube or one parallel to it, eccentrically arranged pockets are provided. The lighting tube itself is of such shape that a quick colliding and separating of the mercury jets flowing simultaneously from the bulbs ensues, so that it is lighted by a small oscillation of 15° or 20°. Six figures.

**15,774/12. Doubling the Frequency of an Alternating Current, also a Wireless Receiver.** M. PLOHL. D.C. and A.C. windings are arranged beside or opposite each other, so that their fluxes mutually link during one half-period, and during the other half-period they form a common field. A secondary winding excited by this field will have double the primary frequency. To obtain continuous action two alternately acting pairs of D.C. and A.C. windings may be connected in series. Instead of the A.C. electromagnetic oscillations may be introduced in the winding, whereby the field so produced may be used to indicate the oscillations. The apparatus may, therefore, be used as a receiver for wireless. Five figures.

**22,364/12. Submarine Telegraphy.** J. GOTT. An extension of the system covered by specification No. 10,534/12 (see ELECTRICAL ENGINEERING, Feb. 27th, p. 120). A double current key and two separate or a split battery may be used. The connections are such that one key transmits current impulses of equal strength (dots), and the other key also transmits impulses of equal strength, but of greater power (dashes). By means of the relays described in the prior specification upon opening either keys the polarity of the current to the line is reversed. Four figures.

**30,059/12. Relays.** F. H. NICHOLSON. A U-tube containing a conducting liquid, e.g., mercury, is pivoted so that it can freely turn. A magnetic flux is maintained by a U-shaped electromagnet directly through the conducting liquid in the central portion of the U-tube through which the feeble currents are caused to pass. The interaction of the flux produced by this current with the permanent flux sets up a flow of the liquid, which therefore rises in one of the end chambers and falls in the other. The centre of gravity being thus disturbed the tube tilts and closes the local circuit. Two figures.

### Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, E.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

Names in italics indicate communicators of inventions from abroad.  
Arc Lamps: SOC. ANON. OFFICINE GALILEO [Remote control of search-lights] 12,449/12; ANGOLD [Magazine] 18,908/12.

Distributing Systems, Cables and Wires, Insulating Materials, &c.: WATERS [Distribution] 11,559/12; BLOUSTEIN [Distribution] 11,584/12; ECKMANN [D.C. motor load equalising] 11,597/12; B.T.-H. Co. (G.E.Co., U.S.A.) [Siliceous insulator] 19,927/12; BOSCH [Bending fibre tubes, &c.] 28,489/12.

**Dynamos and Motors:** LECOCHÉ, 28,766/11; SIEMENS-SCHUCKERT. [Dampers for A.C. machines] 11,957/12; ALLMÄNNA SVENSKA ELEK. AKTIEBOLAGET [Alternator windings] 7,776/13.

**Electrometallurgy and Electrochemistry:** MARKS (Elec. Smelting & Aluminium Co.) [Channel furnaces] 19,607/12; ELLIS [Aluminium nitrides] 25,630/12; ENGLE [Alkaline gelatinous electrolyte] 2,395/13; [Copper oxide plate] 2,396/13.

**Heating and Cooking:** MARTIN [Heater] 12,075/12; CARRON [Gloves and mittens] 18,080/12; MOREAU [Heat radiators] 28,667/12.

**Ignition:** HARTFORD and MASTRANGEL [Engine starter] 14,929/12; BOSCH [Automatically adjusting] 4,693/13.

**Storage Batteries:** MAURICE [Charging and storing cells for hand lamps] 12,505/12.

**Switchgear, Fuses, and Fittings:** SOAR [Woven net resistances] 13,213/12; SIEMENS DYNAMO WORKS and BROOKS [Electromagnetic switchgear] 15,659/12; BERRY and MARKHAM [Iron-clad] 18,349/12; LAKE (J.B.M. Elec. Co.) [Dynamo regulators] 18,425/12; PAGE [Switches] 18,980/12; COX [Controller contact fingers] 19,740/12; SOC. ED. GARBEAU & P. DELAUX [Regulators] 21,813/12; BERRY [Indicators for switches] 22,539/12; HAEFFEL [H.P. connector] 119/13; ELECTROMOTOR EQUIPMENT Co. and BRENNER [Combined locks and circuit breakers for lift gates] 1,433/13.

**Telephony and Telegraphy:** DEGENHARDT [Automatic telephony] 3,987/12; BROWN [Telephony] 4,067/12; DITCHAM, MATTHEWS, and GRINDELL MATTHEWS W.T. SYNDICATE, LTD. [High frequency oscillations for wireless telephony] 6,486/12; MERTON [Wireless] 11,714/12.

**Traction:** ANGUS [Railway signalling] 3,828/12 and 5,916/13; [Point lock control and operation] 5,918/13.

**Miscellaneous:** GRAY and BURNSIDE [Gyrostatic apparatus] 9,246/12; HILL [Lamp signalling] 11,997/12; HOADLEY [Coal-mining] 14,494/12; COLE [Portable self-contained tell-tale and dash-board lights] 23,732/12; ANGEL and CREANE [Fitting lamps to firemen's helmets] 23,814/12; RIETKÖTTER and CLAES [Electromagnetic ore separators] 24,435/12; SMITH [Electrocuting animals] 2,152/13 and 2,199/13; PARSONS and WADDINGTON [Pendulum bell indicators] 4,890/13; KRUPP [Ordnance alarm signal] 5,872/13.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Dynamos and Motors:** FYNN, 11,214/13; SIEMENS-SCHUCKERT. [A.C. commutator motors] 11,315/13.

**Electrochemistry:** SOC. GEN. DES NITRURES [Manufacture of aluminium carbides] 11,091/13.

**Incandescent Lamps:** WESTINGHOUSE METALLFADEN GLÜH-LAMPENFABRIK [Rendering metals and alloys ductile and malleable] 11,017/13.

**Instruments and Meters:** LANDI [Direction indicators] 1,198/13; [Revolution counters] 1,199/13.

**Storage Batteries:** SABLON [Plate protection] 8,469/13.

**Switchgear:** GORTON [Automatic S.P. switch] 608/13.

**Telegraphy:** DOS SANTOS [Stations] 11,243/13.

### Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

**Dynamos, Motors, and Transformers:** SIEMENS-SCHUCKERT. [High-speed commutators] 4,240/07; CROMPTON & Co., J. C. MACFARLANE and H. BURGE [Motor-generator supplying constant current] 3,626/08.

**Electrometallurgy:** K. HIORTH [Reduction of iron ores] 3,680/08.

**Switchgear, Fuses, and Fittings:** W. E. BARTON [Q.B. switches with quick make: also circuit breakers] 3,762/05.

**Traction:** C. DE KANDO [Stator casings for motors in electric vehicles] 3,989/03; W. R. SYKES [Visual and audible signal cabin indication of position of train in block section] 4,406/06; A.E.G. [Pneumatic raising and lowering gear for overhead collectors] 4,263/07; A. SPENCER [Control of gas lamps on trains] 3,779/08; SIEMENS DYNAMO WORKS (Siemens-Schuckert.) [Combined tightening gear and section insulator for overhead contact lines] 4,112/08.

**Miscellaneous:** W. J. RIDER [Advertisements] 4,296/06; R. WAYGOOD & Co. and R. CAREY [Pneumatic gate operating gear for lifts] 4,423/07; J. C. CHALMERS and W. A. ROBERTSON [Number indicators] 3,615/08; K. O. LEON [Steering torpedoes] 3,854/08; A. GREENWOOD [Remote indicator for doors] 20,753/08.

## LOCAL NOTES

**Belfast: The New Power Station.**—With regard to the proposed new power station of the Corporation, a question has been raised as to whether the Corporation has the power to erect a new generating station upon lands not specified in an Act of Parliament or Provisional Order. The City Solicitor has reported his opinion that the Corporation has this power subject to the consent of the Board of Trade, but in view of the importance of the question, the opinion of counsel is to be taken on the point.

**Burton-on-Trent: Overhead Mains.**—The Board of Trade has sanctioned the erection of overhead mains for the supply of electricity to the sewage pumping station at Clay Mills. The Board of Trade reserves the right to reconsider the use of these overhead mains at the end of five years.

**Bury: Electricity Accounts.**—There was a loss of £642 upon the working of the electricity undertaking to March last, compared with a loss of £1,276 in the previous twelve months. It is pointed out in the report that no less than £11,219 have been required for interest and sinking fund charges. The debit balance has been taken from the reserve fund. The revenue for the year was £2,923 more than in the previous year, which is the largest annual increase since the undertaking was established, with the exception of the year when the electric tramways came on to the mains. An arrangement has been made with the Radcliffe Urban District Council to take a supply in bulk from the Corporation instead of extending the Radcliffe Works. A supply under this agreement is now being given.

**Croydon: Electricity Accounts.**—In his annual report, Mr. A. C. Cramb, the Borough Electrical Engineer, calls particular attention to the increase in the sales for power purposes, and also for heating and cooking. He points out that the cost of electric heating is comparatively low, and that this business can be developed much easier than that of cooking, where the cost of apparatus is such that few people will buy it, and he adds that it is hopeless to expect any material increased business in cooking until the Corporation take in hand a satisfactory scheme for developing it by hiring out cookers at reasonable rates. In this connection attention may be called to the I.M.E.A. Bill, which is abstracted on another page, and of which Mr. Cramb has been a most ardent advocate for many years.

**Dromore: Electric Lighting.**—The Board of Trade has refused to grant the Council an electric lighting Order.

**Dublin: Proposed Increases of Salary.**—With reference to the recommendations of the Electric Light Committee to increase the salaries of the City Electrical Engineer, the Deputy City Electrical Engineer, and the Chief Engineer of the Distribution Department, as mentioned on page 282 of our issue for May 15th, a deputation of ratepayers waited upon the Corporation last week to protest against these increases, mainly on the alleged ground that in 19 years the ratepayers have only had £9,000 from the electrical undertaking, which has cost £750,000.

**Durban: Electric Heating and Cooking.**—According to H.M. Trade Commissioner for South Africa, the efforts of the Corporation in encouraging the use of electricity for cooking and heating purposes are meeting with considerable success, and the result of the introduction of a cheap apparatus designed by the Borough Electrical Engineer, is that many electric cooking and heating outfits have been installed.

**Felixstowe: Proposed Purchase of Electricity Undertaking.**—The negotiations with Dr. Liebbrand, who proposed to make an offer to purchase the electricity undertaking from the Council, have been abandoned.

**Halifax: Gas and Electricity Competition.**—A proposal by the Electricity Committee that the charge for current for lighting purposes should be 4d. per unit up to 1,200 units per quarter, and 2d. per unit for all consumption in excess of this amount, has been referred back. The objection seemed to be that an all round revision of the charges by the electricity undertaking, including power consumers, should be undertaken. Oddly enough, the proposal to refer back came from the Vice-Chairman of the Gas Committee, with which the Electricity Committee is in very active competition. In fact, some of the members of the Council are beginning to regard this competition with apprehension, and the Mayor has suggested that if the Gas and Electricity Committees cannot come to some agreement in the matter, the Council must deal with it.

**Hastings: Electric Lighting Accounts.**—There was a net profit of £556 upon the electricity undertaking last year.

**Hull: Electricity Supply.**—A proposal by the Electricity Committee to take over the Hessle electric lighting Order has been defeated in the Council, the vote being 29 for and 20 against. It was pointed out that the principal capital expenditure would be from £10,000 to £12,000, but the Electrical Engineer estimated that on the first year there would be a loss of £500, after which he anticipated profits.

**Lincoln: Electricity Accounts.**—The net profit on the electricity undertaking last year was £2,538, compared with £3,038 in the previous twelve months. The number of units sold increased by 21.5 per cent. during the year, but in spite of the large increase in the price of coal, the amount used per unit generated has been slightly decreased.

**London: L.C.C.**—The County of London Electric Supply Co. has, under a notice served upon it by the London County Council, already established six testing stations in its southern area. As the result of further negotiations three testing stations are now to be installed in regard to the Company's North London area.

**St. Pancras: Street Lighting.**—The Electricity and Public Lighting Committee is to report as to improving the lighting of the main roads of the borough.

**Stepney: Electricity Accounts.**—There was a net profit of £11,507 on the working of the electricity undertaking for the year to March last, in spite of the considerably increased price of coal. This profit is £1,250 less than in the previous year, due to the above cause.

**Manchester: Rateable Value System of Charging.**—The Electricity Committee has adopted the Norwich system of charging, as an alternative rate at the option of the consumer, to the existing tariffs for domestic supplies. The new rate is on the basis of 12½ per cent. on the net rateable value of the dwelling house, plus ¾d. per unit for all current used. The adoption of the new tariff is contingent upon the consumer agreeing to instal for domestic power purposes a certain minimum number of kilowatts, according to the rateable value of the premises, in addition to the existing lighting requirements.

**Peterborough: Electricity Accounts.**—The deficit of £145 on last year's working of the undertaking has been met out of the reserve fund.

**Rochdale: Bulk Supply.**—The question of the terms upon which a bulk supply shall be given to the Heywood Corporation is engaging the attention of the Electricity Committee.

**West Ham: New Domestic Tariffs.**—The following alternative tariff has been agreed to:—The price for all energy used for lighting, heating, and cooking is to be ¾d. per unit, in addition to an annual charge of £10 per kilowatt of lamps installed, with a minimum payment of £2, and 2s. for every additional 10 watts. An allowance up to 25 per cent. may be made for lamps for occasional use. For heating and cooking the annual charge is 10s. for the first kilowatt, and 6s. 8d. per kilowatt for additional apparatus. After the first kilowatt the charges are subject to division into tenths, e.g., 1s. 8d. per 100 watts for apparatus between one and two kilowatts capacity.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

### Generating Stations, Sub-Stations, Mains, &c.

**Australia.**—In connection with the electrification of the Melbourne suburban railways, the following plant is required:—Surface condensers, air and water extraction pumps and motors, circulating water and sump pumps with motors. Consulting engineers, Messrs. Merz & McLellan, 32 Victoria Street, S.W. (See advertisement on another page.)

**Bedford.**—The Local Government Board Inspector, who

recently postponed an inquiry concerning a loan of £11,590 for the purpose of receiving further information, continued it yesterday.

**Belfast.**—A loan of £35,000 is to be applied for in connection with the electricity undertaking, including additional arc lighting.

**South Africa.**—*The British and South African Export Gazette* states that the Kalk Bay and Ermelo Municipalities will shortly be inviting tenders for electrical plant.

**Wigan.**—A new turbo-alternator, &c., is to be installed at an estimated cost of £8,700.

**Worcester.**—Certain alterations are to be made at the sub-stations at an estimated cost of £750, to meet objections raised by the Electrical Inspector of Factories.

**Worthing.**—The new plant, for which, as we announced last week, a loan is to be sought, includes a 260 kw. Diesel engine generating set with provision in the engine room for an additional 260 kw. set and 350 kw. set.

### Wiring

*The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.*

**Aberdeen.**—New buildings for provincial committee for training teachers, costing £49,000.

**Barrow-in-Furness.**—New secondary school.

**Bristol.**—Electric lighting of new wing, General Hospital. Secretary, Guinea Street.

**Bury.**—New mill for Peel Mill Spinning Co.

**Croydon.**—Forty-six dwelling houses, Wharfedale Gardens D. Weighton, 78 North End.

**Derby.**—Additions to Borough Asylum.

**Farnworth.**—New fire station.

**London: L.C.C.**—Electrical installation at the Caldecot Road elementary school, Denmark Hill, S.E. 192 lighting points. Chief Engineer, July 2nd. (See advertisement on another page.)

**Nottingham.**—New cinematograph theatre. Architect, F. Ball.

**Oxford.**—Proposed City museum.

**Paisley.**—Four-storey building for Co-operative Manufacturing Society.

**Ravensthorpe.**—New school.

**Sheffield.**—Infants' Department at Greys Stone school. Secretary, Education Offices. New telephone exchange. H.M. Office of Works, London.

### Miscellaneous

**Birmingham.**—Twelve months' supply of electrical accessories for the Electricity Department. City Electrical Engineer. June 23rd.

**London: Stepney.**—Twelve months' supply of arc lamp carbons. Borough Electrical Engineer. June 30th. (See advertisement on another page.)

**Sweden.**—The Swedish State Railways Administration require 206,700 arc lamp carbons, and 44,100 incandescent lamps. Copies of the specification, &c., may be seen at 73 Basinghall Street, E.C.

### TENDERS RECEIVED AND ACCEPTED

**Liverpool.**—A further order for 4,000 Robertson lamps has been secured by the General Electric Co. from the Corporation, for the purpose of illumination, in honour of the forthcoming visit of His Majesty King George.

**London: L.C.C.**—The following tenders have been received for alterations to the electric lighting on Westminster Bridge:—S. Pontifax & Co., £72 5s.; J. Biggs, £150;

W. Sugg & Co., £216 4s. 6d. The first-named tender is recommended for acceptance.

**Manchester.**—The following tenders have been accepted:—General Electric Co., two 50 h.p. three-phase motors; Siemens Bros. Dynamo Works, Ltd., switchgear, bus-bars, &c.; Holden & Brooke, Ltd., electrically driven boiler feed pump; Bruce Peebles & Co., two 750 kw. motor converters; British Electric Transformer Co., a supply of 75-k.v.a. transformers; W. T. Henley's Telegraph Works Co., and Electrical Engineering & Equipment Co., low-tension cable; W. T. Henley's Telegraph Works Co. and C. Macintosh & Co., paper-insulated and rubber-insulated cable respectively.

### APPOINTMENTS AND PERSONAL NOTES

Mr. M. N. Jacks, director of Humphreys, Ltd., and Mr. J. Norman Ampler have joined the Board of Scholey & Co., Ltd. (151 Queen Victoria Street, E.C.).

Mr. Justus Eck, of the Union Electric Co., has returned from his tour to Australia, Tasmania, New Zealand, Canada, and the United States. In Melbourne he read a Paper on "Indirect Lighting by Arc Lamps," before the Victorian Institution of Electrical Engineers, and received an invitation from the Engineering Society of Queensland to read a paper before that body. Unfortunately lack of time compelled him to decline. Mr. Eck expresses himself satisfied in every way with his tour, and particularly with the cordial reception universally extended to him by members of all branches of the electrical industry.

Mr. H. E. Blain, who has been General Manager of the West Ham Corporation Tramways since 1903, has resigned to take up an appointment elsewhere.

### MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. George Smith & Son, 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £69 5s. to £69 15s. (last week £71 to £71 15s.).

**Benjamin Electric, Ltd.**—Mr. G. Campbell, Sales Manager of this firm, informs us that the accounts and order departments are now managed at 1a Rosebery Avenue (Tel.: City 2407), but the sales offices and showrooms are still at 117 Victoria Street, S.W. (Tel. Victoria 1297).

**Edison & Swan United Electric Light Co.**—According to correspondence in the financial papers, there seems to be some prospects of the debenture consolidation scheme (referred to in our last issue) meeting with opposition by the holders of first debentures.

**The Washington Industrial Property Convention.**—The International Convention for the Protection of Industrial Property, as revised at Washington in 1911, has been signed by the United Kingdom, Germany, Italy, Japan, the Netherlands, San Domingo, Austria and Hungary, Spain, the United States of America, France, Tunis, Mexico, Norway, Portugal, Switzerland, New Zealand, Ceylon, Trinidad, and Tobago, and is now in force between these countries. The Arrangement for the Prevention of False Indications of Origin of Goods, as revised at Washington, has been signed by the United Kingdom, Spain, France and Tunis, Portugal, Switzerland, and New Zealand.

## SUMMARY

THE 18th Annual Convention of the Incorporated Municipal Meeting is being held this week in London. Mr. J. E. Edgcome, the President, in the course of his opening remarks, made allusion (amid applause) to the wrong policy of municipal corporations in imposing an age limit of forty upon candidates for posts of chief engineer; in view of the technical and commercial experience necessary, men over forty might often, he thought, be better fitted for such positions than younger men. He then read an Address by Mr. Shawfield, who had been elected President last year, but had to resign on leaving municipal employ. In his address, Mr. Shawfield expressed himself in favour of extending wiring powers to all municipal electricity departments; he discouraged the allocation of profits to rate relief instead of to building up a reserve fund, the provision of working capital, and expenditure upon extensions and improvements; he looked forward to large reductions in the price of electricity as the initial capital charges were extinguished by the operation of the sinking fund; he suggested that gas supply should ultimately take the form of non-illuminating producer gas, which would be used by the suppliers of electricity for the production of electrical energy; and he reviewed the relations between electricity committees and their responsible officials, recommending that the Chief Engineer should have full control both of the technical and financial side, and that the pay of technical assistants should always be adequate to their duties and responsibilities. (Page 351.)

DR. S. Z. DE FERRANTI opened a discussion on "Prime Movers." Oil fuel, he thought, should be left to the motor-car, the Navy, and the Mercantile Marine, and, in comparing the gas engine with the steam turbine, he gave his reasons for believing that the balance of advantage was with the latter. In the discussion, Colonel Sinclair gave some low steam consumptions of a reciprocating engine suitable for small stations; Mr. Seaton derided the practice of making the contractor carry out the reception tests of plant instead of these being made by an independent expert; Mr. H. S. Russell spoke in favour of a number of scattered Diesel engine stations being used instead of a large steam station with sub-stations; Mr. Chattock had made a comparison of the cost of steam and gas engine stations, which showed a distinct advantage to steam; and Mr. Richardson had obtained a similar result as between Diesel and steam; Mr. Weekes described a method of utilising high pressure exhaust for heating purposes in sugar and soap works; Mr. Gray gave some interesting figures of the economy obtained with his gas engine and bye-product recovery plant; Mr. Wordingham favoured the employment of gas engines of moderate size supplied with gas from gas works; and Mr. Chamen agreed absolutely with Dr. Ferranti. (Pages 353 to 356.)

A REPRESENTATIVE exhibition of heating and cooking apparatus is being held at the Institution of Electrical Engineers during the I.M.E.A. Convention. (Page 356.)

AN extremely practical discussion on electric cooking was held at the meeting of the "Point Fives" on Tuesday evening. It was considered even more important that the hiring charge be kept low than that the price of energy should be put down to  $\frac{1}{2}$ d. per unit. (Page 357.)

To obtain all-round equity a new tariff for electricity supply was suggested in a Paper by Mr. F. Simpson read recently before the Yorkshire Section of the Institution of Electrical Engineers at Leeds and Sheffield. The tariff is based on the analysis of published accounts for the last 15 years, from which, on the author's "business" basis, it appears that very few undertakings make any profit at all. The tariff it is suggested should be subject to yearly revision, but it was severely criticised by several speakers. (Page 360.)

At the Annual Congress of the Tramways and Light Railways Association, held last week at Blackpool, Mr. E. H. Edwards made some suggestions for increasing the profits on interurban lines by the use of less elaborate cars and by encouraging goods traffic. In another paper, Mr. F. Bland reviewed the development of tramway track design. The subject of railless traction was dealt with by Mr. H. England, and Mr. A. V. Mason read a paper on tramway rules and regulations. (Page 361.)

THE Electrical Contractors' Association held their annual dinner on Tuesday (Page 362.)

SOME particulars are given of the Cumberland electrolytic method of preventing scaling and corrosion of boilers and condensers. (Page 362.)

At the last meeting of the Institution of Electrical Engineers a Paper on telephone transmission calculations was read by Mr. A. J. Aldridge, who developed a graphical vector construction applicable to a number of practical problems, and proposed a new reference standard telephone line. (Page 363.)

METHODS of differentiating between alternating and continuous current mains and ascertaining if they are live and if they are carrying current, are asked for in our Questions and Answers columns. (Page 365.)

WE give a few particulars of the electrically-driven model warships used in the display at the Earl's Court Exhibition. (Page 365.)

AMONG the Specifications published by the Patent Office on Thursday last were several relating to telephony and telegraphy. A system of cable protection where there are cables in parallel is covered in a specification by E. G. Waters, and the use of a weight or spring for resetting the carbon catches in magazine flame arc lamps is protected by H. E. Angold. The grant of a patent to C. A. Midgley and A. H. Vandervell for a variable speed constant pressure dynamo is opposed. (Page 366.)

MOTOR omnibus competition has almost wiped out the surplus on the L.C.C. tramways, but measures are to be taken to meet the competition more successfully. Expenditure of £1,000,000 has been sanctioned on the Post Office tube railway. (Page 367.)

SOME notes on the Marconi report are given under Telephony and Telegraphy. (Page 367.)

A CONSIDERABLE advance has been made in the heating and cooking load at Brighton, but the net profit of £1,406 is less than that for the previous year on account of an increase in the rates and price of

coal.—Some of the employees of the Leeds Electricity Department have been on strike, but there has been no danger of interruption to supply.—It has been decided in the Court that in view of the Limerick Electricity Department having charged a price less than the maximum allowed by their Order, they have no power to levy a rate to meet the deficit on the undertaking. (Page 369.)

CONVERTING plant is required at Stepney; cables at Newcastle-under-Lyme; and a switchboard, battery, and booster at Limerick. (Page 369.)

## ARRANGEMENTS FOR THE WEEK

(TO-DAY), THURSDAY, JUNE 19TH.

*Incorporated Municipal Electrical Association.*

10.15 a.m. Annual Convention. Empire Theatre, Kingston-on-Thames. (1) "Air Filtration," by J. Christie (2) "Electric Vehicles," by W. H. L. Watson and R. J. Mitchell, introduced by A. H. Seabrook.

3.0 p.m. Trip to Weybridge.

FRIDAY, JUNE 20TH.

*Incorporated Municipal Electrical Association.*

10 a.m. Annual general meeting at Institution of Electrical Engineers, followed by special general meeting for amendment of Articles of Association.

SATURDAY, JUNE 21ST.

*Incorporated Municipal Electrical Association.*

9.30 a.m. Visit to King George Reservoir, Chingford.

THURSDAY, JUNE 26TH.

*National Physical Laboratory.*

3.0 p.m. Opening of new buildings by Mr. A. J. Balfour.

*Institution of Electrical Engineers.*

9.0 p.m. Conversazione at Natural History Museum.

## The London Electrical Engineers.

(TO-DAY) THURSDAY, JUNE 19TH.—C. Company. FRIDAY, JUNE 20TH.—D. Company. MONDAY, JUNE 23RD.—A. Company. TUESDAY, JUNE 24TH.—B. Company. THURSDAY, JUNE 26TH.—C. Company. FRIDAY, JUNE 27TH.—E. Company. Infantry Drill, 7 to 9 p.m. Technical Instruction for all members of the Sixth Rate and for all Candidates for Higher Rating, 7 to 9 p.m. Musketry Instruction, 7 to 10 p.m.

SATURDAY, JUNE 21ST.—Main Party for Bere Island parade at Headquarters at noon.

SATURDAY, JUNE 29TH.—All Companies parade at Headquarters at 8 p.m. for Ceremonial Parade on Wimbledon Common. Dress: drill order, service dress, black louts and putties. The Officers' Drill Cup Competition will be decided on the turn out for this and the Royal Review Parades. Members are asked to turn up early. Regimental business transacted 10 a.m. till noon.

## EIGHTEENTH ANNUAL CONVENTION OF THE INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION

THE attendance at the Convention of the Incorporated Municipal Electrical Association held in London this week constituted a record. A list of 252 members who had up to Wednesday last week intimated their intention of attending the meeting was published in our last issue, but since then a large number of other visitors decided to come, and the total number rose to about 350. For the convenience of members we prepared a list of names supplementary to that published in our last issue, and this was distributed at the meeting on Tuesday. The number of lady visitors was also exceptionally large.

Mr. J. E. EDGCOMB (Chief Electrical Engineer, Kingston), President of the Association, took the chair on Tuesday, when the Association met in the building of the Institution of Electrical Engineers, and were welcomed by Mr. W. DUDDELL, the President of the Institution.

In the course of his remarks Mr. DUDDELL said that it was extremely appropriate that the Association should have its headquarters in the Institution building. Any advance in the electrical industry affected all sections. Looking back upon the history of the Association, he recalled that when it was started in 1896 it was a very small body, and one criticism levelled at it was that it "hurried" too much. But looking through the proceedings of the last few conventions, it seemed that the members had considered very seriously all the important subjects which affected the electrical industry. His wish was that the deliberations of the present convention would lead to good results, and that any resolutions which might be arrived at would benefit the electrical industry as a whole. He was quite certain that working for the industry as a whole they would promote the welfare of the particular branch in which they were interested.

In tendering the Association's thanks to the Institution, Mr. EDGCOMB said that most of them were, and they all ought to be, members of the Institution, which was the senior institution, and they must feel that coming to this building they were more or less coming home. If he might be allowed to congratulate the Institution through Mr. Duddell, it would be on the formation of the Industrial Committee, which, under the very able chairmanship of Mr. Hugo Hirst, was doing, and would continue to do, very good work for every branch of the profession.

Mr. EDGCOMB then explained why it was that he was not delivering a Presidential Address.

Members, he said, had naturally looked forward to being presided over by Mr. Shawfield, who was unanimously elected last year to the position of President, but in giving up his position as Chief Electrical Engineer at Wolverhampton, Mr. Shawfield had been obliged to give up his position as a member of the Association. The Council had then decided to elect for the remainder of the term a Past-President, and the choice had fallen on him (Mr. Edgcomb). He had felt, however, that the members were still entitled to receive a Presidential Address from Mr. Shawfield, especially as he himself had already given a Presidential Address seven years ago. Although Mr. Shawfield had been obliged to give up his connection with the Association upon leaving municipal work, he hoped that at no very distant date they would be able to bring him amongst them again as an Honorary Member.

### SUGGESTED SLIDING SCALE OF SUBSCRIPTIONS.

There were two other points on which he would like to touch, the first being in the nature of an apology and the second in the nature of a protest. In his Presidential Address seven years ago, he had expressed the hope that at no distant date the Association would start an Information Bureau. But when he vacated the Chair he had been elected Honorary Treasurer, and he was afraid that the enthusiasm of the President had since been somewhat damped by the financial caution of the Treasurer. Consequently, the matter must be delayed until they found some means of increasing their revenue. He would suggest that such a means would be found in a sliding scale of subscriptions or donations from the larger municipalities. At the present time all municipalities, large and small, paid a practically nominal subscription, but it seemed to him that it would be fair that the larger undertakings should pay a larger subscription *pro rata* either upon capital expenditure or profits.

### "TOO OLD AT FORTY."

The second matter, as he had said, was in the nature of a protest. Lately several municipalities had thought it wise to include an age-limit restriction when appointing engineers and managers of their undertakings, and he would like to point out strongly that no possibly good purpose could be served by this.

(Applause.) The fact that there was no such restriction would not in any way tie the hands of a municipality when making the selection of their engineer, and they would be able to select suitable men of any age they thought fit. He considered that in these days, when the Chief Engineer and Manager of a big undertaking had to have experience, not only on the engineering side of the profession, but also on the commercial side, a man who had already had very considerable experience in the generation and distribution of light and power, with all its many and varying responsibilities, must be better fitted to take charge of a large undertaking than a younger man who, from his age, had not had time to get that experience. He was not at all in favour of the view that a man is "too old at forty." (Applause.)

As Mr. Shawfield was unable to be present himself, Mr. Edgcomb then read his address.

### MR. C. E. C. SHAWFIELD'S ADDRESS

THE position of President of the Incorporated Municipal Electrical Association is undoubtedly one which carries with it many and varied responsibilities, and those members of your Association who have passed the Chair will doubtless agree with me when I venture the opinion that the preparation of the Presidential Address is by no means the least of these responsibilities. It is, I believe, the first time in history that the opening address has been given by other than the President for the time being, and I desire to express to you my thanks for the honour you did me when you elected me your President twelve months ago. It was with very real regret that I found myself compelled to lay down the reins of office, owing to my vacating municipal service.

At the time of the formation of the Municipal Electrical Association in 1895, electricity supply was truly in its infancy, and, like most infants, progressed with somewhat weak and faltering steps. In what was quite a large central power station in those days there would often be found a neatly-arranged row of generating sets of sizes ranging from 10 kw. to deal with the day load, up to monsters of 50 or even 100 kw., designed to cope with the peak load, which occurred during the evenings in December. At that time, absolute continuity of supply was a dream seldom realised, and there were few householders or shopkeepers who did not keep a supply of candles and matches in readiness for the expected breakdown. It is difficult to realise that in the eighteen years which have elapsed since the first meeting of your Association was held in London, the electricity supply infant has grown into such a remarkably well-developed and healthy adult, and that it is now surrounded by a numerous and healthy progeny of allied industries and undertakings.

One of the most remarkable features in connection with the growth of electricity supply during recent years is the enormous increase which has taken place in the application of electricity to industrial purposes, and the rapidity with which its status has changed from being that of a luxury to be enjoyed by the few, to that of a necessity which is demanded by the many. A cheap supply of electricity is now as necessary to the welfare of the community, as a whole, as is a cheap and ample supply of water or the provision of a well-designed system of drainage. There can be no doubt that the rapidly increasing use of electricity by manufacturers for motive power purposes has had a marked effect in improving and purifying the atmosphere of our large industrial centres, and this will doubtless have been brought to the notice of many members of this Association by the decreasing frequency of the fogs, upon which many of us formerly depended for the improvement of our lighting load factor.

When reviewing the present position of public electricity supply in Great Britain, and the progress that

has been made since its inception, one is struck by the fact that, so far as the provinces are concerned, the great bulk of the industry is under municipal control, and the question immediately arises—has the progress that has been made, been in spite of, or because of, municipal ownership? As in most matters of policy in this country, public opinion appears to be sharply divided upon this question, and whilst one section asserts that municipal control is essential to the proper regulation of the supply of public necessities, another party as loudly condemns it as being economically unsound. I must confess that after seventeen years of municipal work, I am unable to give my adherence to either of these opinions, because although it is perfectly true that in certain instances electricity supply has languished whilst under local government administration, there are other instances where magnificent results have been achieved, second to none that have been shown by any private enterprise. Moreover, it must be remembered that in certain cases the opponents of municipal trading have done their best to thwart and hinder those who were endeavouring to develop municipally-owned undertakings on business lines, and when their efforts have been partially or wholly successful they have pointed the finger of scorn at their victims and held them up as typical illustrations of municipal mismanagement.

It must be borne in mind that during the early years of electricity supply, the establishment of a central station in many of our provincial towns would probably not have been possible, except for the fact that municipalities were able to raise capital at relatively low rates of interest, and the fact that a large number of small stations have been provided and operated by municipalities under conditions that no private company could have survived, has resulted in a vast amount of valuable experience having been obtained in the design and arrangement of generating plant and distributing systems, of which we are now beginning to reap the benefit. Much has been said for and against the principle of municipal trading in the past, and I have no desire to add further to what is too frequently a profitless discussion. The fact remains, however, that whether for good or for evil, Parliament has committed to the municipalities of this country the control of the supply of electricity to the bulk of the community, and it rests with the members of the Incorporated Municipal Electrical Association to see that this trust is not misplaced.

One of the most curious anomalies of the present position of the public supply of electricity in this country is, that whilst a municipality is empowered to generate and distribute electricity throughout its area, and to make contracts with consumers as to the terms and conditions of supply, it is practically debarred from installing in a consumer's premises the apparatus which is necessary to enable that consumer to utilise the electricity which the municipality has for sale. That is to say, that whilst a local authority is permitted, and even encouraged, to spend tens of thousands in generating plant and distributing mains, it is not permitted to spend tens or hundreds in the purchase and installation of wiring, fittings, and motors. You are told that this restriction is placed upon you because if you entered into the business of supplying fittings and installations, you would be competing with private enterprise, and that you have no right to use money borrowed on the security of the rates to finance a retail trading department. The supporters of this theory apparently ignore the fact that the existence of an electric supply undertaking postulates the provision of means to enable the electricity to be consumed. In London, and in a few of the larger provincial towns, this necessity can be, and is, to a large extent, provided by private enterprise, but many of you who are associated with stations in smaller communities, know

only too well that the average wiring contractor has not the capital or the staff, and too frequently also has not the ability to adequately supply the requirements of consumers. It is true that some municipalities have been fortunate enough to obtain, by means of private Acts, full powers to carry out wiring and installation work of all descriptions and to sell and fix electricity consuming devices. The Corporation of Wolverhampton has possessed these powers since 1899, and after fourteen years' experience of the practical operation of these powers, I can unhesitatingly affirm that both the electricity department and the local wiring contractors are in a flourishing condition. If a municipality has only the restricted powers given under the Electric Lighting Clause Amendment Act—by which wiring work can only be carried out through a contractor—the result is of very little use to either party. I sincerely trust that this Association and the municipalities which it represents will continue to press for the general concession of those powers to all municipalities which are at present confined to a section only.

I am entirely opposed to what I regard as the vicious practice of rate relief from the profits of electricity undertakings [*cheers*], and I sincerely trust that the members of this Association will do whatever lies in their power to discountenance these donations. This subject was exhaustively dealt with by one of your past Presidents about two years ago, and I can only express my heartfelt concurrence with his expressions of opinion. I would go further and say that whilst municipally-owned electricity undertakings should be self-supporting, their surplus earnings should be allocated firstly, to the accumulation of an adequate reserve fund, secondly to the provision of working capital, and that any balance remaining should be devoted to the extension and improvement of the undertaking. It has frequently been stated by one of the inspectors of the Local Government Board that to borrow capital for extensions with one hand whilst giving surplus profits to the relief of rates with the other is virtually equivalent to borrowing money for purposes of rate relief. I cannot help agreeing with him on this point.

Much has been done in recent years in the direction of lowering the average rate of charge per unit to all classes of consumers, but I firmly believe that much still remains to be done in this direction, and that if municipally-owned electricity undertakings as a body were to go boldly for a drastic reduction in prices, they would not only be more faithfully performing their duties to the community as a whole, but they would also reap a rich reward in the shape of increased output and better financial results. As a general principle I believe that practically every central station can afford to sell electricity at a profit, at a lower price than that at which none but a specially circumstanced private generating plant can produce it, and it should be the aim of every undertaking to supply from its mains every unit of electricity consumed within its area. There is a great temptation to enlarge upon this question, but as I have already inflicted upon you one paper on this subject, I must not trouble you farther.

Up to the present the history of electricity supply in this country has been one of constant warfare against gas competition, both for lighting, heating, and motive power, and it may now be safely affirmed that electricity has won for itself an assured and unassailable position as regards public and private lighting and for motive power purposes, whilst it is making a strong attack upon the hitherto impregnable position of heating and cooking. The time is now rapidly approaching when a large part of the present capital liabilities of electricity undertakings will be liquidated by the operation of the sinking fund, and when this day arrives, it seems probable that such a general reduction in the selling price of electricity will be possible that its prac-

# DELIVERIES

OF  
**“FREEZOR”**  
ELECTRIC FANS

## IMPORTANT ANNOUNCEMENT

*re*  
**Express Delivery Service.**

Owing to the vagaries of the British climate and the consequent element of uncertainty that exists with every contractor in deciding what quantity of Fans shall be kept in stock, we have inaugurated a new system of express deliveries which should relieve anxiety in this direction and enable the Trade to fill their orders direct from our stocks with a minimum of delay.

This arrangement should prove of value to all Contractors who are handling “Fans” as it permits of “free” trading on a minimum stock basis.

During the winter months we have accumulated vast stocks of “Freezor” Fans of all voltages at our London Showrooms, and various Provincial Branch Establishments, and can deliver any quantity by return.

*Write for Particulars of this New Delivery Service.*

### THE GENERAL ELECTRIC CO., LTD.,

**Head Office:** 67, Queen Victoria Street, London, E.C.  
Telephone: LONDON WALL 3600 (20 lines).      Telegrams: “ELECTRICITY, CENT. LONDON.”

**Branches:** Manchester, Glasgow, Birmingham, Newcastle, Cardiff, Dublin, Belfast, Bristol, Swansea, Liverpool, Leeds, Sheffield, Nottingham, Hull, Southampton.

**“FREEZOR” FANS**  
EXPRESS  
DELIVERY SERVICE

**"ANGOLD"**  
PATENT  
**MAGAZINE**  
**FLAME LAMP**

The most successful Arc Lamp for the lighting of Streets,  
Public Places, Docks, Railways, Large Engineering Works, etc.

Amongst many Municipalities  
using "Angold" Magazine  
Flame Lamps are the following :

ABERDEEN  
ALDERSHOT  
ASHTON-UNDER-LYNE  
BIRKENHEAD  
BIRMINGHAM  
BLACKBURN  
CANTERBURY  
DUNDEE  
GLASGOW  
GREENOCK  
HACKNEY  
LUTON  
LIVERPOOL  
MANCHESTER  
PAISLEY

Amongst many Municipalities  
using "Angold" Magazine  
Flame Lamps are the following :

PERTH  
POPLAR  
ROTHESAY  
SALE  
ST. PANCRAS  
SOUTHWARK  
STRET福德  
SUNDERLAND  
SUTTON COLDFIELD  
WEDNESBURY  
WILLESSEN  
Etc., Etc.

Used by many leading Corporations for years with highly satisfactory results.

When corresponding with Advertisers, please mention "Electrical Engineering."

tically universal adoption for lighting and motive power purposes will become inevitable.

Hitherto, the competition between electricity and gas has been beneficial both to the competitors and to their consumers, but I have thought that the time may arrive when it may be to the interests of both parties, and of the community generally, that instead of competition, there should be co-operation, the suppliers of gas devoting their energies to the economical production of non-illuminating producer gas, which could be used by the suppliers of electricity for the production of electrical energy. If such an arrangement were possible, it would assist in the husbanding of our coal resources and would bring a little nearer that flat rate of something less than one halfpenny per unit which at present seems rather a Utopian vision.

The question of the management of electricity undertakings, especially as affecting the relations between the Electricity Committee and their responsible officials, is rather a delicate subject, and is usually more suitable for discussion in camera than for an address of this description. The success or failure of any undertaking depends in no small measure upon the degree of confidence which the Committee reposes in their Chief Engineer and Manager, and I would most respectfully urge that the Chief Engineer of every electricity undertaking should be given full control, not only of the technical, but also of the financial side of the department, subject, of course, to the strictest audit by the Accountants' Department and the public auditors. He should have complete control of the general staff of the department, and all matters of discipline and of the remuneration of employees should be left to his discretion. He should also be provided with a competent and well-paid technical staff. I am afraid that in too many cases (some of which I am personally acquainted with) the rates of pay of the technical assistants in some of our large undertakings are entirely inadequate to their duties and responsibilities. The best asset that any electricity undertaking can possess is a loyal and zealous staff, who have at heart the commercial and technical well-being of the concern, and in order to secure this, it is necessary that every member of the staff of every grade shall be made to feel that he is a trusted and responsible official, and that he is adequately remunerated for his services.

In conclusion, I particularly wish to express my appreciation of the real benefit which accrues from membership of the I.M.E.A. The actual work done by the Association through its Executive Council is of the greatest importance to the electric supply industry as a whole, but of even greater benefit than this is the good feeling which is promoted amongst the component members of the Association. It is a surprising, but nevertheless pleasing, fact that any member can practically call upon the experience and resources of the whole of the rest of the members in case of any difficulty which he may encounter, and any assistance that he may ask for is given with the utmost freedom and willingness. I have been a member of the Association since shortly after its formation, and have had the privilege of being a member of the Executive Council for the last seven or eight years, and I much regret that the fact of my leaving municipal work involves my leaving also the I.M.E.A. I particularly desire to thank the members of the Executive Council and the officers of the Association for their loyal co-operation and support during my brief term of office as President, and to express my sincere hope that I shall frequently have the opportunity of renewing the many friendships which I have formed amongst you.

A discussion on the relative merits of steam, gas, and oil generating stations was then started by Dr. S. Z. de Ferranti, who contributed the following short Paper:—

## PRIME MOVERS FOR ELECTRIC POWER

By DR. S. Z. DE FERRANTI.

NOTWITHSTANDING the amount that has been written regarding the different systems of driving electric generators, the subject still seems to be one of considerable interest. The position to-day is that the steam turbine is in possession of the field, and that gas and oil engines are looked upon as likely alternatives. Many people believe that it is only prejudice or the fear of doing something new that prevents engineers from using these two latter methods for generating their power. I do not, however, agree with this view, and believe that engineers are using the only means that are at present economically available for the work they have to do.

Electricity is being produced on a larger scale every day, and it appears certain that to obtain the full benefits of electric working the current must be produced in large stations supplying extensive areas embracing all classes of demand. As we are dealing with prime movers for electric power, I will, therefore, consider the question from the point of view of the comparatively large generating station. The essential qualities of a power-producing plant are reliability and low cost as regards capital running and maintenance. The question before us may be considered in detail under the following headings:—

- (1) Nature of fuel consumed, its availability and cost.
- (2) Amount of fuel consumed per unit generated.
- (3) Standby losses.
- (4) Labour involved in running.
- (5) Cost of upkeep of plant.
- (6) Capital cost of plant.
- (7) Size of units, simplicity or complication.
- (8) Reliability and proved capacity for work required.

As we are a coal-producing country it is evident that coal is our natural fuel. The very fact of oil being so sought after as fuel for certain purposes puts it out of the question for general power production. In the first place, the automobile on land must consume and even now consumes large quantities of light oil. For the Navy oil is so eminently suitable as fuel that the demand in this direction will always raise its price above that due to its heat value. Furthermore, if there is ever a surplus after supplying the Navy, there remains the vast and ever-increasing demand by the Mercantile Marine who will always be able to pay more for it than land consumers could do.

It is, therefore, clear that coal must be our fuel where operations are carried on on a large scale. In the future, the oil consumers above mentioned will even be partly supplied from the bye-products of our coal, instead of our burning any appreciable amount of oil for making electricity. It is, therefore, vital that our power-producing plant should be coal burning. The plant must be made suitable for the fuel, and not fuel found to suit a particular form of machinery.

We have next to consider the thermal efficiency of the plant for producing electricity. By this I mean the percentage of the heat in the fuel turned into current. A good steam turbine and boiler plant will to-day give back 15 per cent. of the energy of the fuel as electricity. As high an efficiency as 18½ per cent. has actually been obtained in practice. It is probable, however, that this is by no means the limit of economy, and that developments in this class of machinery will result in an efficiency of 25 per cent. being obtained in the near future.

The next coal-burning machine that we have to consider is the gas engine. With it we have to consider not only the efficiency of the machine itself, but also that of the gas-producing plant. When the system is considered from this point of view its efficiency is probably between 20 per cent. and 22 per cent. With this process there should, of course, be worked bye-product recovery. Although it appears evident that in the future all coal must be gasified and its bye-products recovered, it does not seem that present knowledge enables this to be done at sufficient profit for it to be generally adopted.

In the oil engine we have a machine which represents the highest efficiency yet realised. Moreover, test figures and those obtained in practice agree very closely. The efficiency as already defined may be taken at between 28 per cent. and 30 per cent.

The question of standby losses may next be considered. In the oil engine there is practically no loss under this heading. In the gas engine there is the producer loss, and in the turbine the boiler loss. These will vary very much with the nature of the load, and where the plant is well designed and run and the load factor is good they may be reduced to a small quantity. Both the oil engine and the

gas engine are, however, badly handicapped in relation to the steam turbine by their incapacity for dealing with overloads which the station must always be in a position to meet.

With regard to the question of the labour involved in running and maintaining the plant; as matters stand to-day the turbine installation is undoubtedly the best, but it is hard to make a direct comparison as the number of generating units with either gas or oil would be so great. It is, however, certain that the plant which is the simplest will always have the advantage, and where one is purely rotary and the other reciprocating there can be no question at all.

In the matter of capital cost the turbine system is again much the best, the simplicity, large units and small space occupied contributing to this result. The size of the units on the turbine system compared with those on the other system is perhaps the greatest determining factor in the case. The turbine is to-day adequate in fulfilling the demand, whereas the other two systems are not. Moreover, combined with its boilers and auxiliary plant, it is a simple means of generating power.

Reliability of operation is, of course, vital, and here again the turbine system scores on account of its great simplicity and because in working its parts are not subjected to either high or uncertain stresses.

In practice the turbine system has proved its capacity to meet the demand that is made on power-producing plant. All this goes to show that the course now followed by engineers in the selection of their plant is the right one, and that they really have no option in the matter. Looking at the question in the light of possible developments of the future, I cannot help thinking that as long as engines are used the rotary principle will be followed. For the moment the steam turbine system will be perfected so as to improve its efficiency and fuel consumption; later on, when the turbine can be made of the internal combustion type better economies will be obtained.

#### DISCUSSION.

COLONEL SINCLAIR (Chairman, Swansea Electricity Committee) said that there were still power stations in connection with individual works, and even for small towns, and perhaps for the linking up of small hamlets where the reciprocating engine still had a look in. His people had comparatively recently had occasion to instal a reciprocating engine of a comparatively new type for works driving, that known as the "Uniflow" engine—Professor Stubbs' patent. This had only two valves, and was a single-cylinder engine with no exhaust valves, the piston in moving from end to end uncovering a number of circular holes in the periphery of the cylinder and allowing the steam to pass to exhaust. In all other respects it was very similar to any other reciprocating engine. He had two of these connected to 300-kw. continuous-current generators with a booster and a 1,000 ampere-hour battery. The load varied from  $\frac{1}{2}$  h.p. to 500. The manufacturers on tests of these engines got well within their guarantee of slightly under 9 lbs. steam per I.H.P. with a 170 lbs. pressure and 225 deg. of superheat. These engines had now been running for two years, and the latest result was that, after a continuous year's working, one of these machines generated  $1\frac{1}{2}$  million units (load factor  $44\frac{1}{2}$  per cent.), and the coal used per unit was 3.62 lbs. The operating costs were:—wages, 0.0934; coal, 0.202; material, 0.0244; repairs, 0.0291, making a total of 0.3489d. per unit. The coal used was 13,500 B.Th.U., the average pressure 165 lbs., and the average superheat 200 degrees. During the coal strike his machines ran for five weeks with 25 per cent. overload the whole time, and that, of course, did not tend to excessive economy. Included in the figures, also, was a large amount of experimental work, the units for which were not metered. He hoped he had made a case for reciprocating engines for small stations.

Mr. G. D. SEATON (Richardsons, Westgarth and Co., Ltd.) said that a few years ago at the Annual Dinner of the Manchester Section of the Institution of Electrical Engineers, Dr. Ferranti was entrusted with the toast of "The City of Manchester and the Royal and Ancient Borough of Salford," and let fly a terrific speech on the iniquities of municipal trading. The great charge he had made against municipal electrical engineers was that they hindered progress by accepting the lowest tender. But it was almost impossible for people who had had no previous experience in steam turbines to avoid accepting the lowest tender. Supposing, for example, a man was in the market for a 2,000-kw. alternator. He would put in the usual advertisements, in which it was definitely stated "We do not bind ourselves to accept the lowest or any tender"—although, of course, they did in nine cases out of ten. In reply to such an advertisement there would be about ten offers, and for a week the engineer was busy laboriously scheduling these tenders, and there might be two or three alternatives to each. Probably it would be found that the only way in which the machines varied from one another was in the matter of price, and this variation on a 2,000-kw. machine might be from £600 to £800 between

the highest and lowest tender. It was quite as likely as not that it would be found that the lowest steam consumption would be associated with the lowest price, and, of course, the engineer naturally wondered why he should not accept that tender. The whole thing rested on the question of tests, and the test was about the most Gilbertian and most incomprehensible thing that he could possibly imagine, for the engineer simply let the makers test their own machines. As a German engineer once said to him, "It is a good arrangement, because you can make the figures what you want." He knew that the engineer supervised the tests, but was there any man among them who dared say that he knew all about "diddling"? His advice was that if they wished to hasten the millennium to which Dr. Ferranti had referred, they should buy their plant on merit and have it tested independently, and, further, they should publish these tests in the papers. If he were buying a turbine himself he would lay it down as a fundamental that, in no circumstances whatever, should the makers have anything to do with the tests. He would entrust the test to the company to which Mr. Michael Longridge belonged (the British Engine, Boiler and Electrical Insurance Company). The tests which he had seen carried out by Mr. Longridge were very different affairs from some of the so-called municipal tests.

Mr. H. S. RUSSELL (Messrs. Mirrlees, Bickerton and Day) said that he could not agree that the claims of the oil engine, and especially the Diesel oil engine, could be dismissed as lightly as Dr. Ferranti had done. He had argued that if electrical energy was required on a considerable scale over a fairly large area, it must necessarily be the best thing to confine all the generating plant into one huge station and distribute it over the area. That, of course, meant extra high-tension transmission, which was one of Dr. Ferranti's favourite things; it meant, also, a large number of sub-stations with motor generators or rotary transformers, and the employment of men in these sub-stations. His contention was that a far more economical scheme was to put down Diesel-driven generators in the sub-stations, and to dispense with extra high-tension transmission and the generating station. There would also be a big gain in efficiency, because of the saving in losses in transmission and in transformation. It was not much use trying to save 10 per cent. in generating costs if they were losing 15 or 20 per cent. in transmission. Dr. Ferranti said in his Paper, "As we are a coal-producing country, it is evident that coal is our natural fuel." That statement, however, contained an economic fallacy, because there were obviously conditions which might arise which might make it advantageous for us to export our coal and import some alternative fuel, such as oil. He would give a parallel case. Ireland was a bacon-producing country, and according to Dr. Ferranti the whole of Ireland should be fed on Irish bacon; but the fact was that the whole of the Irish bacon was exported—the Irishman himself ate imported Canadian bacon. Even if it were admitted that coal was the best thing to use, it did not follow that steam-raising was the best use for it. Dr. Diesel had said in his Paper before the Institution of Mechanical Engineers last year that as tar and tar oils are three to five times better utilised in the Diesel engine than coal in the steam engine, a much better and more economical utilisation of coal is obtained by first transforming it into coke and tar by distillation, using the coke in metallurgical and for other heating purposes, and burning the combustible bye-products and part of the tar itself in the Diesel engine under exceptionally advantageous conditions. In the *Engineer* of October last year it had been stated that by special processes for the production of tar oil from bituminous coal, as much as 18 gallons per ton, or 40 per cent. of the coal, could be converted into tar oil, and as the fuel consumption in the Diesel engine was probably less than one-quarter that of the steam engine, it was obvious that even with coal as a fuel the Diesel engine had the great advantage. There were other advantages which everybody was well aware of, such as the absence of stand-by losses and the fact that the engine was ready for starting up at a moment's notice. Comparisons of steam and oil station costs also overlooked the wastage of coal during storage, which might amount to anything from 10 to 25 per cent. There was one other point, namely, the question of supply and the price of fuel oil. Where oils were distilled for the purpose of obtaining petrol and other light oils, it was the residual that was made use of as fuel in the Diesel engine, so that it was obvious that the greater demand there was for petrol the greater would be the supplies of Diesel engine-oil available. The present high price of fuel oil was not due to monopolies or any rigging of the market, but was entirely due to the want of transport facilities for bringing the oil over. As soon as the tank steamers which are now being built came into service, oil would go down to its normal price again, and there was no reason to trouble about a shortage for 100 years. His firm was full with orders for Diesel engines for a long time to come, and those who were contemplating putting down Diesel engines could do so now in the full knowledge that fuel oil would be cheap again before they could obtain delivery of their engines.

Mr. R. A. CHATTOCK (Chief Electrical Engineer, Birmingham) said that the criticisms of Dr. Ferranti's Paper which had been made were hardly justified by his own experience. Recently he

was in want of a very large plant in Birmingham to deal with his extensions and developments, and had made a comparison between steam and gas-generating plant. With the capital cost of the plant, the cost of labour for working interest, and sinking fund, fuel consumption, and all the items usually considered in works costs taken into account, he had ascertained that for a producer gas station working on a load factor of 27 per cent., which was about the average to be anticipated in Birmingham, the cost per unit was 12 per cent. higher with gas than with the steam plant. Also in the case of a gas-driven station using town gas of high calorific value—about 500 B.Th.U. per cubic foot—and reckoning gas at 6d. per 1,000 cubic foot, the working costs were 41 per cent. higher than steam. He agreed that a 27 per cent. load factor was considered low for a gas-driven station, but plant of this kind would have represented eventually something like 70 per cent. of the generating plant in the undertaking, and therefore it was impossible to treat it differently from the steam plant already there. The size of the units which he considered for the steam turbine plant were 5,000 kw., and for the gas plant 4,000 kw., which was the largest that had been commercially made up to the present. He also considered 1,000 kw. gas-engine sets, and the figures worked out slightly higher than in the 4,000 kw. sets, chiefly due to the extra cost of labour in running. This brought him to Mr. Russell's recommendation of Diesel engines in substations. For an undertaking requiring 100,000 kw., which was quite a usual figure nowadays for the large towns, it would be necessary to have something like 200 Diesel oil engines, and the labour cost of handling those engines appalled him. Dr. Ferranti had drawn attention to the incapacity for dealing with overloads which oil-driven stations suffered from. This was a very important point when it was necessary to call upon the plant to deal with sudden emergencies due to breakdown or fogs. Reliability and continuity of supply were things which must always be kept in the front rank of requirements.

Mr. R. W. WEEKES referred to the statement in Dr. Ferranti's Paper that "A good steam turbine and boiler plant will to-day give back 15 per cent. of the energy of the fuel as electricity, as the high efficiency of 18½ per cent. has actually been obtained in practice." He, however, wished to talk about a steam plant which he had installed in various places in large units, in which 83 per cent. of the heat that the engine took was turned into electrical energy. The 81½ per cent. of the energy of the fuel which is not being turned into useful work went into the circulating water, and in the works they would be visiting that afternoon, was simply warming the Thames. Unfortunately they were obliged to waste that heat in most instances, but there were a large number of works and factories, such as soap works and sugar refineries, where steam heating was required. In these places low pressure boilers were installed in which the steam was made at 60 lbs. and used at 12 lbs. They burned coal in very much larger quantities than municipal electricity undertakings, and it was usual to find 800 tons of coal being burned in a week: he knew one case in which the figure was 2,000. If in these works high pressure boilers were installed, working with high superheat, and the steam was passed through a turbine, and then used for the heating process, there was very little loss. In one works in which this method was used, only 6 per cent. of the total heat in the steam was lost. In a particular works in 1900 he put in high-pressure boilers and high superheaters working up to 700 degrees. The engines were Easton engines, and the steam consumption was down to under 16 lbs. per kw. hour. He went back to those works in 1908 or 1909, extended the high-pressure boilers, but instead of highly economical steam engines he used a simple steam engine with one expansion. The maximum load on that plant was only 400 kw. The steam was taken into the engine at 200 lbs., and was turned out at 65 lbs. The steam consumption in the engine was 65 lbs. per kw. hour, but the nett result of the change was that in 1911 a saving of 4,000 tons of coal was made, and between the years 1909 and 1911 the expenses were reduced by £3,000.

Mr. H. GRAY (Chief Electrical Engineer, Accrington) said that they had all had experience with steam turbines, but he was probably the only member, so far, who had had experience with gas bye-product plant. At Accrington he had had such a plant in operation for eight months. It was not justifiable to give any accurate costs for anything less than 12 months' running, but he would mention a few leading details. He had two 1,000-h.p. units, with ammonia- and tar-recovery plant, &c. His object had been only to let the gas plant deal with a 24-hour load (i.e., 100 per cent. load factor), and to let the steam plant take the peaks, and he had almost realised this, as one or other of the sets had been running all the eight months at an average of 82 per cent. load factor. A 100 per cent. load factor was not attainable owing to the unfortunate occurrence of Sunday with its very light load. The plant had never been held up yet, although turning out 86,000 units a week. The fuel for the last three months had averaged 1.56 lbs. per unit, corresponding to 0.125d., and the bye-product plant produced 0.01d. per unit, which was therefore more than half the total fuel costs. This result had been attained with local fuel (Lanca-

shire steam slack), and if he had gone further afield for his coal he might have shown lower costs still. He noticed that Dr. Ferranti's costs did not include stand-by, and he should therefore mention that the cost of keeping a 1,250-h.p. producer ready for work within a quarter of an hour was only that of half a ton of coal a week, which was quite negligible compared with the fuel required for stand-by with boiler plant. For taking overloads, steam plant was, of course, the best, but, when working in the manner he had indicated, the steam plant took the overloads, and it was equivalent to putting a steam cylinder on a gas engine. Finally, he said that he could run a gas engine up to speed in 20 seconds, and could synchronise it within a minute.

Mr. E. E. HOADLEY (Chief Electrical Engineer, Maidstone) said that they could not all be engineers of such large stations as had been mentioned by Dr. Ferranti and Mr. Chattock. A short time ago, when he was preparing to put in a new 750-kw. set, he obtained the guaranteed oil and steam consumptions from makers of the two classes of engines, and as he knew from his own practice the lbs. of coal per lb. of steam, he was able to make a comparison of the fuel costs in the two cases. On the basis of the 2½ million units which would be supplied next year by that set alone, and taking account of fuel, labour, lubrication, repairs, and capital charges, he had found that steam would be cheaper.

Mr. C. H. WORDINGHAM (Chief Electrical Engineer, Admiralty) said that most of them were familiar with Dante's Inferno, but they were all familiar with what he might call Ferranti's Paradiso. All of them present thought of the future to some extent, but perhaps the Paradiso when only large-scale generation would be in existence was a good way off. They must remember that small generators would continue to be used for some time, and to interest a good many people. Some few months ago he ventured to air his views on this subject, and suggested that a good deal of good might come to the electrical industry by generating electrical energy in those places where the demand was small by means of gas engines. He had been soundly thrashed, however, by both sides, but naturally he was still of the same opinion. A great deal might be done by means of gas engines of moderate size supplied with gas made by those who had made it the business of their lives to produce gas cheaply.

Mr. H. RICHARDSON, Vice-President (Chief Electrical Engineer, Dundee), said that, in view of Mr. Chattock's comparison of steam and gas engines, the meeting might be interested in hearing similar comparisons between steam and oil engines. He had found that a 5,000-kw. turbine, complete with its auxiliaries, boilers, and coal bunkers, would cost £30,000, and, from the maker's own figures, four Diesel sets would be required for the same work, and their cost would be £58,000. This was exclusive of the value of the extra space required in the latter case. The fuel costs in the case of the Diesel set would be 0.15d. per unit, as against 0.1d. per unit with the steam sets in use at his generating station at Carolina Port (or, say, 0.11d. per unit, as the price of coal had risen). Moreover, the coal market was less unsteady than the oil market, and as to the future of the latter he had only interested prognostications to go upon. There was a field for oil-engine stations in rural and other smaller districts which were chiefly residential and not industrial. He could not see Mr. Russell's loss of 15 to 20 per cent. loss in transmission. There might be that loss in the distributing mains for an hour or two a day, but there was certainly not 15 to 20 per cent. transmission loss on the whole output of the station. Mr. Gray had said that the occurrence of Sunday was unfortunate, but for those running internal-combustion engines it was very fortunate indeed. He also pointed out that the costs of a water-power plant were not necessarily less than those of a coal-driven station. He had made inquiries in Europe, Canada, and the United States, and had found that, if account were taken of the capital cost of the civil engineering work in connection with the water supply and the long transmission lines, it was hopeless to compete with the costs of steam plant. In Switzerland, for instance, electrical energy was sold at 50 to 60 per cent. higher prices than to large engineering works in this country.

Mr. W. A. CHAMEN (South Wales Electrical Power Distribution Company), said that he was at one time minded to go in for huge gas generating stations, and one great reason that he had not done so was the difficulty of getting satisfactory generating sets in large units. All that the makers could offer him was a lot of small sets, or some big sets built up with a lot of small cylinders. When he was in trouble two or three years ago, with the coal strike in South Wales, he thought he might get assistance from oil as fuel under his boilers if the coal supply was interrupted. There was a large amount of oil available on the other side of the Bristol Channel at the Avonmouth Docks, but the Great Western Railway Company would not take it through the Severn tunnel, and he would have had to pay carriage on it right round by Gloucester. The price of oil was not the least disappointing item, and it was impossible to put one's finger to a price which could be relied upon. There were, nevertheless, cases in which oil engines

could be used with advantage, and Dr. Ferranti had hinted at them. He had had seriously in view the putting in of a 150 kw. or a larger oil engine as a stand-by to a particular generating station, in which the plant was not of a very economical type. Under the conditions, however, it seemed wrong to spend capital upon this stand-by plant, and therefore, in the end, he kept the station more or less under-steamed, coupling up the Lancashire boilers into a thermal heating system, all the blowouts being connected together, and all the inlets, &c., the boilers being filled up to the neck, and by burning one boiler it was possible to keep the whole lot hot, in order to deal with any emergency at short notice. Although not entirely satisfactory from the purely engineering point of view, it was the best practical solution he could arrive at in that instance. Mr. Russell seemed to imagine that sub-stations must have attendants, but that was not so at all. As a power company engineer he endorsed entirely the views that had been put forward by Dr. Ferranti.

THE PRESIDENT (Mr. J. E. Edgecome) said that before calling upon Dr. Ferranti to reply he would like to say a word, particularly in reference to what had been said by Dr. Ferranti that the navy and marine service would take the whole of the oil fuel coming into the country. The only hope he had at Kingston, where, like Mr. Hoadley at Maidstone, he was running quite a small station, was to run on water gas tar. In fact, he would be doing this soon, as already some very interesting runs had been made, but the only difficulty at the present time was to get hold of the tar, because it seemed to be almost a universal practice to ship the tar direct to Germany, where they dealt with it and recovered the various by-products. It seemed that in the future, unless something was done, we should be shipping water gas tar to Germany, and then arranging to import water gas tar from there to England.

Dr. S. Z. DE FERRANTI, in the course of his reply, said that he had been much impressed some two years ago, by the plant at Gary, on Lake Chicago. At the great steel works there, where gas was a by-product, and there was an ample supply of good quality from the blast furnaces, they had installed some sixteen 2,000 kw. gas engine-driven alternators. The engine-house was an immense one, the installation was fairly big, 32,000 kw. altogether, and it was working under conditions which gave it every chance. There was a practical demonstration of the thing on a fair scale; why was it that the Commonwealth Edison Company, one of the biggest makers of electricity in the world, who made about as much as all London put together, did not instal a similar plant and put up producers to work it by? All that he could say was that the Commonwealth Company were money makers, their living depended upon supplying the public at a sufficiently low rate, and they had found that it did not pay them to do this. Their latest station, North West Power Station, was started up with 20,000 kw. turbine units. Since then they had ordered from Sir Charles Parsons a 25,000 kw. unit, and they had just contracted for a 30,000 kw. machine from the General Electric Company (U.S.A.). It was a most fortunate thing that Mr. Gray, of Accrington, had put down gas-engine plant, which he was quite sure it would pay his Corporation to use, and it was going to be of immense service to the community in getting experience in a most important direction. This experience would help to supply a link in the chain which went to form the future work of generation when all the coal would be turned into gas. If the system described by Mr. Weekes were used generally all over the country, we would be overflowing with sugar and washed away with soap. Mr. Chattock had had to solve a definite business problem, and he was satisfied that it had been solved in the most efficient way that was at present available. Mr. Russell ably represented Messrs. Mirrlees, Bickerton & Day, the makers of Diesel oil engines. Mr. Day was an old friend of his, and he had had the opportunity of seeing the splendid works which had been erected here for the manufacture of Diesel engines, where they were produced in as perfect a manner, from the scientific and business point of view, as one could imagine, and he was delighted to know—what he knew before Mr. Russell spoke—that notwithstanding the high cost of oil, the firm had business which would occupy them to the fullest extent for at least two years. It only showed that it was fortunate that municipal electrical engineers did not depend on Diesel engines for generating electricity, because under the circumstances the supply would run very short. As to Mr. Hoadley's remarks, when he commenced to speak, he (Dr. Ferranti) had made the note that he would not pretend to recommend steam for comparatively small sizes, but Mr. Hoadley had told them that as the result of an actual trial, by getting the prices, he had found that it paid to instal steam. Dealing with the question generally, he thought it would be a very desirable thing if municipalities and companies could work together and avoid the installation of these small generating units and small generating stations, and in spite of the fact that he entirely disagreed with municipal trading, it would also be a good thing to the same end if municipalities could supply outside the areas at present allotted to them. He could only say that, as municipal trading was in existence, let municipal electrical engineers do it well.

## EXHIBITION OF HEATING AND COOKING APPARATUS, &c.

AN interesting exhibition is being held during the run of the Convention at the Institution of Electrical Engineers of electric heating and cooking apparatus and other appliances connected with the domestic uses of electricity. This display, which has been organised for the Incorporated Municipal Electrical Association by the British Electrical and Allied Manufacturers' Association, is being held in the "Common Room" of the Institution to the left of the main entrance, where some twenty selected firms have prepared representative displays. For the convenience of our readers we describe these in the order of their position, commencing on the right of the doorway of the first room.

The first stand we come to is that of A. P. Lundberg & Sons (Liverpool Road, N.), who have a case full of samples of their well-known products in the way of switches, plugs, and other installation material, including the ingenious two-way intermediate and other switches of which they developed such a complete series covering every possible variation of single and multiple lamp control. Considerable help is given to the understanding of the uses of these by the ready wired-up demonstration awards that are also shown. There are many points of detail in the apparatus that repay close examination.

On the adjoining stand Ferranti, Ltd. (Central House, Kingsway, W.C.), make a fine show of some of their latest heating and cooking appliances. Some artistic patterns of their electric-fire type of radiator with its glowing disc of quartz, are on view; and the cooking apparatus, in which the leading feature is the use of a single pattern of readily interchangeable disc-shaped heating unit, includes examples of small ovens, a table cooker with hot-plate on the top and grill below, and simple hot-plates in various forms, all of good substantial construction.

The Electrical Co. (122-124 Charing Cross Road) exhibit heaters of the Bastian quartz type, but their stand is more devoted to the small motor and its domestic and other applications. Small motors are shown both alone and coupled to fans, small drilling machines, &c., and such kitchen appliances as mincing, slicing, and potato-peeling machines.

In the corner of the first room is a complete cooking range, exhibited by Bertram Thomas (Worsley Street, Hulme, Manchester). The Gray patent oven included in this apparatus is solidly made, with large heat capacity and well lagged to retain the heat. The disposition of the heating elements is such as to maintain a good circulation of air inside the oven. Control is partly by means of a series parallel switch at the side of the oven at the bottom. The hot-plates, &c., at the top are controlled by switches ranged along the side.

Passing to the next room and still keeping to the right, we come to the stand of the Dowsing Radiant Heat Co. (105 Great Portland Street, W.) It goes without saying that this company have an excellent display of radiators both of the familiar lamp type, of which they were the pioneers, and of their newer "hot bar" pattern with quartz-embedded heating elements. A special point about the latest form of these is the way in which the back part of the inside of the case is illuminated by a lamp so that the spaces between the glowing part do not appear dark. An extensive show of electric irons is also made, from the largest to the smallest, and special attention should be paid to a rack of heavy tailors' or laundry irons, arranged so that when laid in the rack they plug into suitable contacts for heating-up automatically, and are free from the inconvenience of a flexible lead when in use. It is, of course, to large irons of considerable heat capacity that this method is particularly suitable.

Siemens Bros. Dynamo Works, Ltd. (Caxton House, Westminster, S.W.), have a stand of varied interest surmounted by a row of lanterns for outside use containing high candle-power Wotan lamps. The well-known "Z" cartridge fuse is represented in several forms and sizes, and other exhibits include fans and examples of meters of various descriptions.

Messrs. Berry, Skinner & Co. (78 Upper Thames Street, E.C.) show the latest patterns of their well-known ironclad switches, including their "Dreadnought" fused switch with red and green glass reflex indicators, showing at a glance whether the switch is on or off. In the "on" position of the switch the red glass is held up in front of the green one, but falls out of the way when the switch is off. Another

ADVERT. OF THE GENERAL ELECTRIC CO. L<sup>2</sup> 67, QUEEN VICTORIA STREET, LONDON EC

WHEN CORRESPONDING WITH ADVERTISERS. PLEASE MENTION "ELECTRICAL ENGINEERING."

**Before you can come to any safe decision** as to where to place your lamp contract for the forthcoming lighting season, there are many vital points which should receive full consideration. You must look beyond the advertisements in the Trade Press—look past the reputation of the lamp itself, and consider the organisation which manufactures and distributes.

**A successful lamp and a successful organisation** are your guarantee of successful sales.

**The OSRAM Lamp of to-day has an enviable record.** Consumers are satisfied that it is the one lamp on which they can absolutely rely, and you know the value of your customers' good-will.

We have created the demand by extensive advertising direct to the consumer, and ensured its retention and increase by manufacturing what is known as the **Strongest Lamp** and the **Lamp with the Longest Life**. In face of such facts your choice must be

*When corresponding with Advertisers, please mention "Electrical Engineering."*

part of their stand is devoted to a display of the well-finished forms of teapots, coffee-pots, chafing dishes, and other apparatus recently put on the market by the Brompton and Kensington Accessories Co., for whom Messrs. Berry, Skinner & Co. are agents.

The stand of the Reason Manufacturing Co. (Lewes Road, Brighton) is largely devoted to their well-known electrolytic meters, which are shown in several sizes down to their very compact midget meter for 10 amperes, which is no more than  $6\frac{1}{2}$  in. by 3 in. by  $2\frac{1}{4}$  in. in size. The working of these meters is demonstrated by an illuminated model so proportioned that the movement of the indicating column of mercury as it is displaced by the accumulating gas can readily be seen. Other specialities include a neat and compact complete service set including meter, fuses and sealing box all in one small case. A convenient form of hand lamp is also shown.

A display of electric fans has been arranged by Feld Bros. (25 Budge Row, E.C.), who also show a few radiators and portable instruments.

One of the most interesting stands is that of the General Electric Co. (67 Queen Victoria Street, E.C.), who have a fine display of the various sizes of their "Magnet" irons, and such self-contained apparatus as kettles, toasters, breakfast cookers and table grills in many varieties, such as have been described in our columns from time to time. They also exhibit a new 8-ampere, 220-volt oven, of which they have just made a thousand for the Australian market, and have sent a sample to each member of the "Point Fives" to be tested. The oven is fitted with a thermostat on Nightingall's system. At the side of the oven is a thermometer, and contacts are made when it registers 200, 300, 400, or 500° F. A controlling switch can be set to cause a magnetic cut-out to break the circuit when any one of these temperatures is reached, and to cut the heating elements in again should the temperature fall below the point selected.

Another very complete exhibit of electric heating and cooking apparatus is that of the Electric and Ordnance Accessories Co. (Cheston Road, Aston, Birmingham), who show complete "Eclipse" cooking ranges in more than one size as well as a host of such small self-heated domestic appliances as milk heaters, saucepans, kettles, urns, toasters, small water heaters, hot-plates, &c. Radiators and fans are also shown.

The stand of Venner & Co. is principally devoted to their well-known time switches, and to examples of the Chamberlain & Hookham meters.

The British Thomson-Houston Co. (Rugby) have several types of electric kettles on show, and attention should be directed specially to an enamelled kettle which is provided with an immersion heater attached to the lid, and removable with it, avoiding the inconvenience of the flexible lead being attached to the kettle itself. Examples of their well-known "Calorite" irons are to be seen, as well as their latest designs of radiators for offices, business premises, &c., in cast-iron frames, both with heaters of the lamp and wire patterns.

The British Westinghouse Electric and Manufacturing Co., Ltd. (Trafford Park, Manchester), devote some of their space to a display of meters of various patterns, and also show a type of voltage regulator which we believe is new. Of heating and cooking apparatus proper they have a selection of irons, breakfast cookers, kettles, and other apparatus, as well as a few examples of radiators.

Lastly, we have the stand of the Armorduct Manufacturing Co. (6 Farringdon Avenue, E.C.), where are shown the latest forms of the "Magic" self-contained vacuum cleaner, a portable blower of similar construction, and a new form of electric oven. The bright outer casing of this, which carries the heating element distributed all round its inner surface, is counterbalanced after the manner of a gas holder, and is capable of being lifted clear of the shelves supporting the material to be cooked, while still retaining the hot air. Wiring material is also shown.

## MEETING OF THE "POINT FIVE" ASSOCIATION ON TUESDAY EVENING

A MEETING not on the official programme, but nevertheless practically a part of the proceedings of the Convention, was a dinner of the "Point Five" Association on Tuesday evening at the "Delico" electric restaurant, followed by a general discussion on the extension of the use of electricity for domestic purposes. Mr. A. S. Blackman (Borough Electrical Engineer, Sunderland) presided, and delivered the following address after expressing satisfaction at the

# IMPORTANT NOTICE.

The New

## "ALKLUM" ACCUMULATOR

Is now Ready for SALE

### SPECIAL ADVANTAGES

Contains no Acid. Contains no Lead.  
Has no Celluloid Case.

### STRENGTH

Cannot be hurt with overcharging or running down to Zero.

**SIZE** It is less than any other Accumulator.

**WEIGHT** Is the Lightest in the World.

**LIFE** Has Ten Times the Life of Lead Accumulators.

**CONVENIENCE** Has very wide charging rates.

### RELIABILITY

The voltage keeps practically the same all the time the cell is used.

### GUARANTEE

Is sold with a guarantee that it is superior to any other Accumulator in the World.

They may be seen at the

**MOTOR LIGHTING CO.,**

**13 Pantan Street, Haymarket,**

where all those interested will be welcomed and receive full explanations.

Fully descriptive Catalogue sent on application to the makers:

**WORSNOP & Co., Ltd.**

LAMP WORKS.

HALIFAX, Eng.

large numbers. They had originally expected about 30, but actually 120 diners had come.

#### The Association.

As many of those present are aware, the "Point Five" Association has sprung from the suggestion, thrown out by Mr. Seabrook at Harrogate last year, to form a  $\frac{1}{2}$ d. per unit Dining Club, among the Managing Engineers of Undertakings supplying electricity for cooking and heating, at the rate indicated. The idea was warmly taken up, and the first meeting, held in July last, when seven Managing Engineers were present, representing, with one exception in consequence of illness, every undertaking in the country supplying electricity for domestic purposes at  $\frac{1}{2}$ d. per unit.

Since that date several meetings have been held, at which the dining feature has been a diminishing quantity, and the technical discussions have absorbed an increasing proportion of the time; in fact, the subjects demanding urgent attention have been so many that the last meeting was devoted entirely to the consideration of tariffs and apparatus.

The meetings of the Association have already been productive of valuable papers by the engineers responsible for the initiation of the '5 tariff in Poplar, Southampton, Luton and Bradford, and we have avoided the trouble so many older institutions and associations experience, in obtaining papers, by changing our Chairman at every ordinary meeting. The Chairman is responsible for an address, which is supposed to occupy five minutes—actually takes about ten, and frequently gives rise to a discussion lasting two or three hours. These discussions are of an intensely practical nature. In addition to tariffs and apparatus, selling and publicity methods, and, in short, everything pertaining to the advancement of electricity supply for domestic purposes comes within the purview of the Association.

#### The Tariff.

So far as private houses are concerned, the time is now ripe for a general forward movement in the direction of making the electricity supply entirely supplant the gas service. This can, of course, only be done by the adoption of electricity for such purposes as cooking and heating, and many other domestic uses, and no serious progress can, under ordinary circumstances, be expected, unless electricity is sold, for purposes other than lighting, at not more than  $\frac{1}{2}$ d. per unit. Where this has been done, and the sale of heating and cooking and other consuming devices energetically pushed, the load and diversity factors obtained from private houses has improved in a surprising manner. Put shortly, the load factor obtainable from private houses is largely what the tariff makes it, provided always that the supply is pushed by an energetic sales department; and this proviso is necessary, because the applications of electricity to various household uses are continually increasing. Heating and cooking by no means exhaust the multifarious uses which are developing; as vacuum cleaners, small motors, and other accessories account for quite a large number of units, without making their presence felt from a plant and mains capacity point of view.

With regard to the unit charge, we, in Sunderland, tried  $\frac{3}{4}$ d., and as the result of a good deal of activity, a number of consuming devices were sold and put into use; the consumers were pleased with the comfort and convenience, but the cost of using was so great that we were faced with the alternative of either letting the apparatus fall into disuse, and of abandoning our cooking and heating development for the time being, or of materially reducing the unit price, which was accordingly reduced to one halfpenny.

With few exceptions the electricity supply undertakings throughout the country are in a position to supply electricity for heating, cooking, and miscellaneous domestic uses at this price. The tariff has been for some time in extensive and growing use in places of such divergent characteristics as Poplar, Southampton, Bradford, Marylebone, Luton, Barnes, Reading and Sunderland, and as the result of experience with the tariff the responsible managers of these undertakings are energetically extending the use of it.

An objection sometimes urged against the development of a general domestic load under the '5 tariff is the fear that consumers, having discovered a good thing, would come on at such a speed that generating plant would prove insufficient, mains and services be found inadequate, and other troubles of a similar nature materialise. It is probable that these fears largely arise from lack of experience, and it is questionable what proportion of those suffering from them appreciate that the diversity of a heating, cooking and miscellaneous domestic load is in order of 20 to 1. If the rate was reduced to  $\frac{1}{4}$ d. per unit or less, there would still be no fear of

consumers coming on faster than the supply authority wanted them, and since the sales department was organised in Sunderland, some three years ago, nothing in connection with it has impressed me more than the control a selling department gives over the development of the load. A well-organised sales department can develop, or, if need be, check, the load in any desired direction; and everyone with experience of the working of the '5 tariff will agree that anything in the nature of the load running away with one need not be feared for a moment.

The greatest stumbling block to the development of electrical heating and cooking in towns which have adopted the '5 tariff is the cost of the apparatus, and it is to be hoped that electricity supply undertakers will appreciate that the lack of a low-priced tariff throughout the country is largely responsible for the prevailing high prices. Manufacturing costs are largely dependent upon quantity, and as manufacturers have at present to look for their principal market to a comparatively small number of towns, it follows that when the number of these is greatly increased, as it assuredly will be in the near future, the market for heating and cooking and other similar apparatus will correspondingly expand, and prices drop.

#### The Mechanism.

And now just a few words with regard to apparatus. While the "Point Five" Association is doing all it can to standardise domestic tariffs, I would ask manufacturers of consuming devices and accessories whether they cannot assist the object we have in view, and incidentally themselves, by standardising in some respects. I know that this is a thorny subject, and one frequently met with the reply that standardisation spells stagnation, but the truth of that must depend upon the degree of standardisation attempted.

The plea that it is too early to attempt standardisation will not avail, because one of the accessories most in need of attention has been in use in approximately its present form for the last fifteen years or more; I refer to the plug and socket. The requirement is that the spacing, diameter and length of the pins be defined for standard amperages, and yet, after all these years, it is often impossible to send a consuming device out, wired up to a plug, with any certainty that it will fit the consumer's sockets of similar ampere rating. There are upwards of ten different spacings and diameters of 10-ampere plug pins in use, and the chaos is so great that plugs rated at the same amperage in the same house are often not interchangeable; and matters tend to get worse rather than better. The benefit resulting from the standardisation of plugs and sockets would be immense. It is surely a pity that the inherent advantages of many portable domestic consuming devices should be discounted in consequence of a lack of concerted action.

Another point upon which standardisation might well be considered is with regard to hot-plates. Overall diameters and the position, sizes and conformation of the terminals and fixing arrangements could surely be uniform; and the design of the hot-plate the same whether for use in the top plate of a cooker, as a heating element of an oven, or as an independent piece of apparatus. In mentioning standardisation to manufacturers one is apt to be met with the reply that the manufacturer in question has been fully into the pros and cons of design, and that the expenditure of a considerable amount of time and money has satisfied him that his particular designs are preferable to all others, and that he would not regard it as an advantage to turn out cookers to which other makers' hot-plates could be fitted.

But I ask manufacturers to consider the matter from the electricity supply manager's viewpoint. The position is that electricity supply undertakings will from now onwards expend considerable and increasing sums of money upon heating, cooking, and other domestic consuming devices and accessories for hire purposes; and the quantity of apparatus that can be so placed will very largely depend upon the rates at which it can be hired. In arriving at these rates, considerable regard will have to be paid to the risk of obsolescence, because, notwithstanding the state of reliability to which the articles in question have now attained, it will not be disputed that the near future is likely to witness further improvements, and the consequent depreciation to existing stock could undoubtedly be greatly minimised by such a measure of standardisation as would ensure interchangeability of parts.

I have been requested to say that the Association will welcome expressions of opinion as to whether radiant or convected heat is preferable for ovens. The question is one upon which considerable difference of opinion prevails, some people being of opinion that radiant heat is best for meat, and convected for bread, while others suggest that convected heat

is better for all classes of oven work; and it would be of great assistance if settled ideas regarding the comparative value of the two heats prevailed. In connection with this point it must be borne in mind that an oven which may be an outstanding success in the south of England, where people for the most part do not bake their own bread, may be a failure in the north, where, speaking generally, they do.

## DISCUSSION.

Dr. S. Z. DE FERRANTI, who opened the discussion, said that it was very largely a question of price, which would settle the use of electricity for domestic purposes. Between two and three years ago he had tried unsuccessfully to get the I.E.E. to start a campaign. The only result, however, had been the informal discussions on the causes preventing the more general use of electricity for domestic purposes, from which as yet little had resulted. What had to be done now was to extend the scope of the Point Fives Association so as to bring in as many as possible to follow its enlightened lead. So long as there were only a few giving the low tariff they could not give the benefit of an extended market to manufacturers, so that they could reduce the price of the apparatus. As time went on, a better load factor would be obtained. It wanted someone to discover a method by which a 24-hour load factor could be obtained by taking an equal current over the 24 hours, and giving out the heat as required by the consumer.

Mr. J. H. BOWDEN (Chief Electrical Engineer, Poplar) referred first to the various criticisms—anonymous and otherwise—sent to him as the first Chairman of the Point Fives. For instance, he had been asked how could he sell at a lower price than his generating costs? To such letters he replied that it was not his business to teach the writers their job. The main point, he said, was to arrive at an assessment of the primary charges, not an assessment by another department but by the Engineer, so that each charge should bear its proper proportion to the capital cost. It was a great convenience, for instance, to be able to tell a man who took a house that the charge for lighting would be so much, no matter how much light he used. It should be their endeavour in some way to get rid of the running costs altogether, say by selling by-products.

Mr. A. F. BERRY (British Electric Transformer Co.) congratulated the Point Fives upon having wakened up the country. It was nine years, he said, since he had taken out his first patent for electric cooking apparatus; he had had to wait a long time for a development of this branch of the industry, but now the price charged per unit was lower than his most ambitious dreams. There were, however, still difficulties, on account of the necessity of obtaining a rental; people objected often to paying 10s. 6d. a quarter, and perhaps a "straight rate," higher than 0.5d. per unit, would be the best. He regretted that there were not more "straight" people. A consumer preferred to pay 1d. a unit and know that it was 1d. a unit, to paying 1d. a unit and guessing what it was. There were thirty municipal authorities who hired his cookers, and ten different rates. Possibly one of the things which retarded development of heating and cooking was the former insistence of canvassers that there is "no heat in electricity."

Mr. H. H. HOLMES (Sales Manager of the Marylebone Electricity Department) said that the cost of a complete range to the consumer must be comparable with that of a range for gas or coal cooking. He had found (rather to his surprise) that the cost of a complete electrical equipment for commercial cooking purposes was actually less. The charge for hiring must be fixed at a suitable figure; if too low, it might mean a loss to the Department, so that the business would have to be abandoned; and if too high, the business would not be developed. His experience was different to that of Mr. Berry, for he found that rentals up to £3 a year could be obtained. The cost of maintenance could not be judged until about two hundred cookers were on the mains, and then a fair average could be struck. He found that about 25 per cent. of the cost of the cooker was a rental which would cover cost and maintenance. To include part of the maintenance charge in the cost per unit was not fair to those who bought their cooking plant outright. He expressed surprise at the use of the word "canvasser" by corporation engineers. One never heard of manufacturers depreciating their salesmen by talking of "canvassers"; they called them "accredited representatives." He strongly believed in the policy of sending out cookers on approval, and he found at Marylebone that the returns were less than 8 per cent. Lady demonstrators were also a necessity, and in rich districts more important than in middle class. In one house there had been a succession of six cooks, and each successive one had condemned the electric cookers, and had to be taken in hand by a lady demonstrator. This was not altogether an evil, however, as four of them went to other situations and insisted there on having electric cooking. In Marylebone the cooking business was developing at such a rate that it was at present merely limited by the time required to obtain delivery from the manufacturers. He insisted that more attention should be paid to larger sized radiators. They should be sufficiently large to heat the room, and this was more important than that they should have a nice appearance.

When an inquiry was made for a radiator the first question that should be asked was, What is the size of the room?

Mr. T. ROLES (Chief Electrical Engineer, Bradford), explained the system of charging in use there, which he found that the consumers preferred. The charge was 3s. in the £ on the rateable value of the house, plus 1d. per unit. This was not ideal, but was understandable by the multitude, who did not know what a kilowatt was or what they could get for it. It had made an enormous increase in the output, and during the last two years the average price obtained per unit had been 1.69d. They had worked the tariff out on the basis that the 15 per cent. on an average just covered the lighting accounts, so that the additional 1d. was practically for heating and cooking.

C. R. BELLING said that, if the cost of apparatus were to be reduced, the Sales Departments would have to be content with a lower discount than they now demanded. It was very hard to compete with the cost of gas fires, as quite good little gas fires could be purchased for 35s. net. The question of standardisation was very difficult. His company was now getting out a new 5-ampere plug, and had decided upon  $\frac{1}{2}$ -in. centres and pins  $\frac{1}{2}$  in. long by  $\frac{3}{16}$  in. diameter, but they were open to alter this if it was shown that any other size would be better. It was his experience that, in cooking meat, it was best first to use radiant heat for about half an hour to sear, then to use convected heat for the actual cooking, with a little radiant heat again for the final browning. Radiant heat was also very useful for bread baking.

Mr. R. W. HUGHMAN expressed the opinion that they need not fear being swamped with cheap units which were more likely to make them float with increased buoyancy. He recommended co-operative publicity on a very big scale.

Mr. HAYDN HARRISON expressed his disagreement with everybody who had spoken. Dr. Ferranti, he said, could not have his 24-hour load unless he could persuade everybody to have meals at different times. [Dr. Ferranti here explained that Mr. Harrison had not understood what he had said, and repeated the substance of his remark with regard to the 24-hour load.] Continuing on this point, however, Mr. Harrison spoke of the large output of gas for cooking at midday on Sundays. It was also, he said, a wrong time to talk about standardising when one found that one cooker took double the energy of another. On the other hand, such details as plugs and sockets should have been standardised years ago.

Mr. M. C. H. CLINCH, who is the proprietor of the Restaurant, said that he had first taken on an electrical restaurant a little over two years ago. Being an American, he acted on the principle that "it would not hurt him to try it once." He had found this quite successful, and had in consequence taken the Delico Restaurant, where they served from 1,200 to 1,500 lunches a day. In such a case the initial cost of the outfit was not so important as the annual costs, and he was glad to say that, beyond a fixed charge for the lifts, he had had no maintenance expenses on the apparatus at all. On the other hand, he found great advantages in working compared with gas or coal cooking. He spoke altogether in a most enthusiastic manner about the results.

A wire was then read from Mr. HUGO HIRST, wishing the Association an enjoyable evening and success to their cause.

Mr. R. W. SCHOFIELD (Ferranti, Ltd.) said that as a consumer he thought the price should include hire; a tenant of a house did not want to buy his apparatus. He thought that standardisation as to the shape of cookers would be dangerous, and did not favour standardising the current consumption for hot plates, as this would bear hardly on those which were more efficient. Standardisation, he thought, should rather take the lines of stating the maximum size of the apparatus, stipulating for interchangeability of units, saying whether switches should be on the cooker or the wall, specifying fuses for each unit, earthing, &c. Such things as fixing a definite size for cookers, or whether they should have top side or bottom heat, should not be standardised. He said that a supply company without a showroom should be ashamed of itself, and suggested that contractors should stop asking for apparatus on sale or return, but should pay a sum, say about £10 a year, for the privilege of using the Corporation or company's showroom.

Mr. F. S. GROGAN (British Electric Transformer Company) regretted that membership of the Association should be confined to engineers who charged only 1d. per unit. He was in favour of a lower hiring charge and a higher charge per unit. At Derby, for instance, within a few months, 70 cooking consumers had been obtained, and the charge was 1d. per unit and 4s. per quarter for hire of the apparatus, with free wiring. This, he maintained, was better progress than had been made at Sunderland at 1d. per unit, and required a far smaller selling staff. He deprecated the standardisation of ovens by the "Point Fives," and said that a Point Five oven would be only half an oven unless the manufacturers were with them. He argued that there was no difference between radiant and convected heat in a cooker, and that it was all a question of temperature.

Mr. H. GRAY, designer of the electric oven made by Messrs. Bertram Thomas, and Mr. ROSE, spoke briefly, and were followed by

Mr. B. SANKEY (Chief Electrical Engineer, Whitehaven), who  
(Concluded on page 362.)

## PRICES CHARGED FOR ELECTRIC POWER

A PAPER with this title, by Mr. S. Simpson, was discussed by the Yorkshire Section of the Institution of Electrical Engineers at Leeds on April 16th and at Sheffield on April 23rd.

A review of the returns of many electrical supply undertakings throughout the country would indicate, said the author, that in comparison with most industries an adequate and true profit on capital invested is not being made.

In whatever form the capital is raised it must be repaid by an annual charge on the undertaking before any true profits can be taken out of the business. Of the factors which must be taken into account, so as to arrive at the deterioration which has taken place in an undertaking, the chief consideration is obsolescence, for unless adequate provision is made, a time must arrive when an amount will have to be debited to profit and loss account, which should in strictness have been borne by previous years. The improvement producing this obsolescence might be a very serious competitor to present methods, but would not itself carry a sufficient profit margin to cover the dead weight of interest on capital expended on the superseded plant, &c. This obsolescence would run right through the undertaking to the land and buildings since each is adapted to meet the original needs of the other. Since the depreciation rate must be considered purely as an estimate, the view that residual value be regarded as an asset at the end of the life period appears more reasonable than a prior valuation which in itself could only be an approximation liable to large error. Of the alternative methods of dealing with depreciation, the author commends the principle of an annual charge, but the appreciation and renewals funds should be kept separately; but he favours the methods in which a fixed percentage is taken annually out of the receipts. From a survey of the past 15 years or more he thinks that an average depreciation within 15 years should be allowed for, and local authorities should treat it exactly as an ordinary business undertaking would.

Analysing the published returns for 1912, the author deduces two tables: (A) covering 21 local authorities of 16 to 28 years' working, each with 2,000-kw. or more of plant, and with total capital costs per kilowatt of plant, £60 or less; and (B) covering 38 local authorities of 7 to 15 years' or less working, each with 2,000-kw. or more of plant, and with total capital costs per kilowatt of plant, £60 or less. These distinctions were adopted so as to see what advantage the younger undertakings had had from the earlier development work of the older ones.

The amortisation of the capital account on a 15-year basis to bear  $3\frac{1}{2}$  per cent. interest on outstanding principal is taken as an annual charge per £100 of capital expended of £8 14s. This figure covers depreciation and minimum interest; to this amount must, therefore, be added working expenses, including cost of fuel, oil, waste, water and stores, wages, repairs and maintenance, rents, rates and taxes, management, salaries, office, legal and insurance expenses, and set against revenue account before contingencies and true profit can be arrived at. On this basis only a few of the undertakings show any substantial profit. In the case of Table A the total net production costs per unit sold are 1'44d., and in the case of Table B 1'328d. (the units sold being 325 million and 169 million respectively), while the average prices obtained are 1'375d. for A, and 1'23d. for B, thus showing a loss of 0'065d. and 0'098d. respectively. The standing charges are 0'823d. and 0'663d. in the two cases, and the works costs come out to 0'617d. and 0'665d. To bring about "financial stability" by obtaining an increased price per unit, new tariffs are evolved. The charges arrived at are based on a 24-hour unrestricted service, and questions of contingencies and profit are eliminated. In Table A the stand-by plant is 30 per cent. of the total installed, and in B 25 per cent. The capital costs per kw. installed are £48'75 and £42 in the two cases. From this the author deduces a standing charge of £6'05 per kw. of plant in the first case, and £4'85 in the second, to which he adds the average works cost graded for different load factors according to a certain scale, varying in the case taken from 23 per cent. reduction at from 5 to 10 per cent. load factor to a maximum of 27'5 per cent. reduction at from 20 to 40 per cent. load factor.

The charges so deduced come out as follows:—

Load Factor.	A.	B.
5 per cent.	4'3470d.	3'7870d.
10	2'4580	2'1710
20	1'4400	1'3280
40	0'8635	0'8135
80	0'5520	0'5360

From this table it appears that the present prices charged for supply at load factors up to 10 per cent. are generally remunerative, and that the losses are made on the supply at higher load factors, i.e., on industrial power supply. Unless the tariff is based on these lines all round, equity is not obtained. The author suggests that accounts should be subject to revision annually with regard to (1) diversity obtained, (2) correct maximum demand, and (3) power factor in the case of A.-C. supply. In the latter case 0'8 is taken as the standing power factor. For unity power factor a rebate of 20 per cent., and for a power factor of 0'75 an increase of the standing charge of 17'5 per cent., increasing to 131 per cent. in the case of 0'5 power factor is suggested.

In order that the tariff shall be equitable, a minimum annual payment equivalent to half the estimated total revenue should be enforceable. In conclusion, the author draws attention to the fact that where an outside supply is given to an industrial concern the productive value of the extra capital thus set free, which if a private plant were installed would be required, should be taken into account in fixing a competitive charge.

### DISCUSSION AT LEEDS.

Mr. T. ROLES (City Electrical Engineer and Manager, Bradford), in opening the discussion, said that it appeared from the tables that Bradford was making the handsome profit of minus 10 per cent. However, about five years ago they were making a net profit of £2,000. The experiment was made of increasing the charges for power from 1d. to 1½d., but the power users were up in arms against the increase, and the load did not increase. The speaker then prevailed on his committee to cut the price down again, with the result that the load rapidly improved, and last year the net profit rose to £9,000. The Author based his figures on the endeavour to give equity to all classes of users, and although this was excellent in theory, it was practically impossible of realisation. They could afford to lay a main specially to a mill requiring 200 to 300 kw. at the present prices, and obtain their profit from the lighting load and small power users. If these large consumers were not to be supplied they would have to confine themselves to a small area and increase the charge for lighting.

Mr. WRIGHT was of the opinion that where profits have been shown they have been made at the expense of the small consumers. He had made a comparison of the relative cost of driving a mill by steam taken from actual costs, and the same mill by electricity calculated from results obtained in actual practice. The total annual cost for 711 i.h.p. was £1,586, allowing all charges, which was equal to 4½d. per loom per week. With electric driving he figured it out at £4,273, or 1s. per loom per week. It was apparent that on the question of power supply only, electricity at present prices could not compete with steam; any suggestion to raise the prices would therefore be folly.

Dr. R. POHL (Chief Engineer, Phoenix Dynamo Manufacturing Co., Bradford) did not consider there was any necessity to wipe out all the capital costs in 15 years, and the high value of the standing charges as shown by Mr. Simpson he thought was largely responsible for the poor results shown in the tables. He agreed that at present the lighting consumer paid for the power load which enabled present profits to be made. We had, however, only touched the fringe of the possible private house demand, and if the prices were reduced the number of users would increase so rapidly, both for lighting and cooking, that no increase in the price of power supply would be necessary. Referring to the question of power factor, he would point out that this could be increased by using squirrel-cage motors of larger power than at present allowed, instead of slip-ring motors.

Mr. H. S. BINNS (Leeds) supported the Author, and instanced Coventry, which showed a profit of 17 per cent. Taking both of the tables together, about 25 per cent. of the stations showed a slight profit. Criticising Mr. Wright's figures, he said that actual results show the cost of electric driving to be 5d. per week per loom, and not 1s. The cost of power in weaving cloth is only equal to  $\frac{1}{4}$  per cent. of the total cost of manufacture.

Mr. R. H. CAMPION (Borough Electrical Engineer, Dewsbury) said that until they could get some satisfactory system of storage to cope with the maximum demand it would be necessary to provide stand-by plant, which meant increased capital cost and standing charges. It was these items which required relative reduction, instead of the prices for power being increased.

Mr. J. E. SCHOFIELD (Sales Manager, Yorkshire Electric Power Co.) thought that as manufacturers have increased the prices of their goods 5 per cent. to 15 per cent., and did not find business decline, the same ought to result in the case of power supply.

The discussion eventually developed into a more or less informal talk, in which Mr. Wilson Hartnell (Chairman) and Messrs. E. S. Rayner (Doncaster), J. C. B. Ingleby (Leeds), W. Lang (Leeds), and H. Brown (Bradford), took part, the general feeling being that it was hopeless to think of increasing the charges for power.

Mr. SIMPSON, in replying, said the period allowed for writing off capital was originally high, but it had now been cut down considerably. Improving the load factor and increasing the turnover would not be any advantage unless they brought their fair share of profit.

#### DISCUSSION AT SHEFFIELD.

Mr. H. E. YERBURY (Chief Electrical Engineer, Sheffield Tramways) considered 15 years was too short a period for the repayment of loans. Sheffield in 1912 obtained 30 years for the Tramways Power Station and cables. One must not lose sight of the fact that the majority of the municipal supply stations were not a burden on the rates, and it was not their function to make large profits.

Mr. H. A. NEVILLE (Corporation Electricity Works, Wakefield) agreed with the main principle of 15 years' repayment, but would vary the period of repayment for each section of the capital outlay. He did not support the opinion that the lighting consumer was paying for the losses on the power supply. It was obvious that the long hour consumer at a low price is more profitable than a short-time user at a higher rate.

Mr. W. N. Y. KING (Sheffield) considered it would not be equitable to charge large and small consumers their share of works cost in proportional rates to their demand. The running costs would, to a certain extent, be independent of the load factor, and a heavy load would demand a larger generating set, which of itself would be more efficient. It was quite sufficient for municipal supply stations to pay their way.

Mr. J. C. B. INGLEBY (Leeds) said that he would like to cut down the cost of buildings, subways, &c., and to extend the period of repayment.

Mr. E. J. MARSH (Electrical Superintendent, Sheffield Tramways Power Station), taking the consumer's standpoint, referred to the competition with gas, which in Sheffield was at the low price of 10d., making it impossible to increase the charges for electric power with any prospect of success. He considered it was a mistake to have so many methods of charging—a customer wanted to know in plain figures what it was going to cost him, without a number of conditions. He considered a flat rate based on the number of units used would be preferable to the more elaborate systems suggested.

Messrs. J. E. Schofield, F. J. Lowe (Leeds), W. E. Burnand (Sheffield), and the Chairman, Mr. W. B. Woodhouse (Thornhill), also spoke, after which the Author, in replying, said they had to feel their way and consider the matter from every point of view before settling down to a definite system of charging.

## THE CONGRESS OF THE TRAMWAYS AND LIGHT RAILWAYS ASSOCIATION

THE Fifth Annual Congress of this Association was held at Blackpool on Thursday and Friday last. The mornings were devoted to the discussion of Papers, and excursions were made in the afternoons. The members and visitors were entertained at a banquet on Thursday by the Mayor and Corporation of Blackpool, and a dance ended the proceedings on Friday.

On the first day's meeting, a Paper was read by Mr. E. H. Edwards (General Manager, Lancashire United Tramways Co.), entitled "Possibilities for Increasing Profits on Interurban Lines." The author thought that in tramway undertakings of this nature, as distinct from city systems, economies might be effected by the adoption of less elaborate uniforms, saving of car body maintenance by simpler construction and decoration. He did not agree with Mr. Hooghwinkel that the track should be lightened, especially in view of the increase of motor lorries using the same roads. There was often extravagance in overload construction which could be avoided. With regard to increasing revenue, he encouraged the development of goods traffic in competition with the motor lorry. This, if successful, would decrease the wear on the track by these vehicles, and incidentally reduce the track maintenance. Also a large proportion of the goods traffic could be run at night, and the load factor of the undertaking would be much improved.

The next Paper, by Mr. F. Bland (Edgar Allen & Co.), reviewed tramway-track practice from 1883 to 1913, showing the gradual development from the Marshall patent automatic point of 1882 to the forms now used. The various forms of track rail used at different times, culminating in the British Standard rail, were reviewed, and the successive use of chilled iron, crucible steel, and manganese steel for points and crossings was traced. The details of modern track were summarised, and it was mentioned that mechanically controlled points were now quite out of date, being superseded by electric point controllers.

The first Paper to be read on the second day was by Mr. H. England (General Manager, Yorkshire (West Riding) Electric Tramways Co.), on "Railless Traction Legislation." The author explained how the clauses in the Light Railway Act of last year relating to railless traction came to be mutilated and finally dropped, so that expensive and lengthy procedure by private Bill

still remains the only course. He then proceeded to give digests of 15 Acts which had been obtained by local authorities and three by companies. These comprise Dundee, Leeds, Bradford, Chiswick, Rotherham, Halifax, Northampton, Aberdare, Brighton, Hove, Sheffield, Keighley, North Ormesby &c., Stockport, Ramsbottom, Chesterfield, and Rhondda. (Of these only Dundee, Leeds, Bradford, Rotherham, and Stockport are as yet running.) In these Acts the time of completion allowed generally varies from two to five years, and in most cases the form of the vehicles has to satisfy the Board of Trade. The degree to which carriage of parcels or goods is allowed varies very much; only Brighton and Stockport have full powers. In some cases the use of trolley vehicles is allowed for the conveyance of sanitary refuse, road materials, &c. It is usual for the Board of Trade to take powers to make provisional orders authorising the use of trolley vehicles on new routes. It is apparently not possible to obtain powers in the same Act for subsequent conversion of trolley routes into tramways. Through running is only allowed for at Stockport. Trailers are not usually contemplated, but may be used by consent of the Board of Trade at Ormesby and Rhondda, while the consent of the County Council is also required at Keighley. The cost of road widenings is shared in varying proportions by the road authority and the operators. The road maintenance question is the most important. The Rotherham undertaking contributes 3d. per car mile, with an annual minimum, but may have to pay more if this turns out inadequate, and somewhat similar conditions obtain in Brighton, Chesterfield, Sheffield, Keighley, and Ramsbottom. In Rhondda, however, the liability is definitely limited to 3d. per car mile.

There are various protective clauses regarding bridges, gas mains, drains, &c., and in some cases undue onus as to clearing snow is put upon the operators. In Brighton the local omnibus company is prohibited from working the same routes, and the Keighley Corporation is prohibited from competing with railways, but in general no attempt is made to prevent competition. Some costs of railless traction schemes are also analysed in the Paper. At Bradford the working expenses come out at 6'62d. per car mile, compared with 4'65d. at Leeds and 6'61d. at Rotherham. These do not include interest, sinking fund, &c., which bring the Leeds figure up to 6'76d. and that for Rotherham up to 7'81d. Finally, brief descriptions are given of the leading systems. The "Cedes-Stoll" system is in somewhat extensive use on the Continent, and is to be employed at Keighley and Aberdare. The current collector is a frame carrying a weighted pendulum running on wheels on the top of the two overhead wires, and turned by a flexible cable with a spring drum on the car to take up the slack. Gearless hub motors are employed. The "R.E.T." system, with two trolley poles and two separate geared motors, one driving each wheel through chains, is in use at Leeds, Bradford, Dundee, and Rotherham, and is being installed at Rotherham. The Bremen system used at Stockport has the negative above the positive wire, with a special collector turned by a flexible cable. A single motor drives through a propeller shaft. The "Filovia" system uses a single pole, on which a four-wheeled trolley is mounted.

The final Paper, by Mr. A. V. Mason (General Manager, South Metropolitan Electric Tramways), dealt with the rules and regulations for tramway employees which have recently been published by the Association.

**Faraday House Journal.**—In addition to the usual extensive account of the most recent doings of "Old Faradians," the Summer Term issue of the Faraday House Journal contains abstracts of some Papers read before various societies, reviews of books, an interesting article on the inductive coupling of oscillatory circuits, by Mr. F. C. Topham; and notes on electric winding plant for collieries are contributed by Mr. G. O. Scampton; while the calculation of transformer regulation on inductive loads is dealt with by Mr. J. Goodman. There is also a short biography of Mr. Haydn T. Harrison.

**The San Francisco Congress in 1915.**—Arrangements are now advancing regarding the International Engineering Congress, which is to be held in 1915 at San Francisco in connection with the Panama Pacific International Exhibition. The Congress is to be conducted under the auspices of the American Society of Civil Engineers, American Institute of Mining Engineers, American Society of Mechanical Engineers, American Institute of Electrical Engineers, and Society of Naval Architects and Marine Engineers, and the necessary committees have been formed. The Papers presented at the Congress will naturally be divided into groups or sections. During the Congress each section will hold independent sessions, which will be presided over by a chairman eminent in the branches of engineering covered by his section. The scope of the Congress has not as yet been definitely determined, but it is hoped to make it widely representative of the best engineering practice throughout the world, and it is intended that the Papers, discussions, and proceedings shall constitute an adequate review of the progress made during the past decade and an authoritative presentation of the latest developments and most approved practices in the various branches of engineering work.

## THE "POINT FIVES" MEETING

(Continued from page 359.)

suggested that membership of the "Point Fives" should be open to all engineers actively engaged in pushing heating and cooking apparatus, especially those engineers charging on the Norwich system. He then instanced his own district, where one of his best customers kept a model lodging-house with beds at 3d. per night. Slot meters were used, and the charge was 5d. per unit, of which 4d. was returned at the end of every month on those units, registered on a separate meter, which had been used for heating or cooking. In addition, a charge of 5s. per quarter for a cooker, 2s. 2d. for a breakfast griller, and 1s. 6d. for a hot plate, was made.

Mr. NAPIER PRENTICE (Chief Electrical Engineer, Felixstowe) spoke on the question of radiant *v.* convected heat for cooking. The former roasted and the latter baked. Cookers should be designed to have both. He had found that the best efficiency was obtained with a cooking temperature of about 220° F. with a preliminary roasting; though the time taken was longer than in a coal oven, yet the losses were only 3 to 4 per cent. against 25 per cent. He had been greatly struck with the automatic and time switches now largely used on American stoves. He thought that it was a mistake to make the hiring charges too low, as had been done by the gas companies, who were now finding out their mistake. He did not think that it was necessary to reduce the price of electricity as low as ½d. per unit.

After some remarks by Mr. N. MILLER (E. & O.A. Co.) and Mr. D. HUNTLY (Dowsing Co.), Mr. H. R. BARGE (Chairman, Poplar Electricity Committee) proposed the health of the "Point Fives," coupled with the name of the Chairman, and Mr. Blackman briefly replied, and defended the Point Fives against some of the criticisms levelled at them during the evening.

The meeting adjourned about 11.40 p.m.

## THE CONTRACTORS' ANNUAL DINNER

**A**BOUT eighty members and friends attended the dinner of the Electrical Contractors' Association under the chairmanship of the President, Mr. W. A. Shaw, at Frascati's Restaurant, on Tuesday evening, when excellent fare both as regards refreshment and speeches was provided.

The toast of the evening, that of the Association itself, was proposed by Mr. M. N. Drucquer, whose forensic eloquence is well known to all who have followed the Association's victories in the law courts. He congratulated them more, however, on their success in the peaceful settlement of disputes than on their fights, and enlarged upon the ability of Mr. Tate, their secretary, both as a negotiator and as an expert witness. The Association seemed always to accomplish successfully what it set out to do. Its membership was rapidly increasing, and already they had bolted and barred the door of 50 Corporations who had attempted to get wiring powers. He referred to the famous Leicester case, and how at Sheffield their craft had been preserved from extinction. It was essential to maintain the present solidarity of their organisation. Safety was to be found as much in unity as in numbers.

Mr. S. H. Webb, the president-elect, in his reply, said that the Association only resorted to law as a last resort when peaceful methods failed, and reminded them that in every case fought under the able leadership of Mr. Drucquer and advice of Mr. Tweedy-Smith had been successful. He now looked to more peaceful times. The Association was now stronger financially and in other ways than it had ever been before. They all wanted to cultivate a better understanding with the station engineers, whom they regretted had lodged a Bill in Parliament that they could not agree to. He complained that municipal balance sheets did not reflect truly the work of the fittings departments, and the competition was not fair. He wished that the engineers would only treat with them so that they all could work amicably together. In conclusion he appealed particularly to London contractors to join the Association and take advantage of combination where individual action had not the ghost of a chance.

At this point an illuminated address was presented to Mr. A. Davidson in recognition of the work he had done in connection with the Sheffield campaign, and Mr. W. R. Rawlings, in making the presentation, said that the settlement of the Sheffield case would prevent many municipalities from attempting the same action. Mr. Davidson replied, paying tribute to the work of Mr. Drucquer and Mr. Tweedy-Smith in the struggle, and declared in a fighting speech that it was his intention to carry the matter further through the Chambers of Commerce, and to insist on an impartial audit of all municipal accounts. Another illuminated address, accompanied by a cheque, was then handed to Mr. Tate by the Chairman, with congratulations on his recent marriage, which were suitably acknowledged.

Mr. E. C. WALLIS, in a clever speech, next proposed the kindred associations, referring to the good work done by the Scottish Contractors' Association, the Ironmongers' Association, and other bodies.

Mr. S. E. EDGCOMBE (Borough Electrical Engineer, Kingston-on-Thames), responded for the I.M.E.A. It was difficult to voice the very divergent views of all the components of his Association, but speaking personally, his own undertaking had had full wiring powers for 13 years, and worked most amicably with the contractors, to whom practically all the work was given by acceptance of the lowest tender. The Electricity Department practically acted as banker to the contractors, and protected them against all possibility of bad debts. He hoped that peaceful means might be found of getting over the present troubles, and emphasised that all were really members of the same profession. He looked forward to good work from the Industrial Committee of the Institution of Electrical Engineers.

Mr. Tweedy-Smith then proposed the health of the chairman, who in his reply referred to the good work done for the Association by Mr. McDermott, Mr. Marryat, the Secretary and the proposer of the toast.

## THE CUMBERLAND PROCESS OF AVOIDING CORROSION

**W**E have received from the Cumberland Syndicate (44 Charing Cross, S.W.) some particulars of the Cumberland electrical patent process for avoiding corrosion, pitting and scale in condenser tubes and boilers, which is in use with considerable success on sea and land in various parts of the world. It has long been realised that deterioration of condensers, boilers and such vessels, &c., is largely due to electro-chemical action, and it has been met to some extent by immersing in the vessel a piece in metallic contact with the casing. The zinc, being electro-positive to the metals of the vessel, takes all the corrosion to itself, so to speak, and all the other metal work forms the negative pole, and a protective liberation of hydrogen takes place over its surface, effectively preventing corrosion. This is, however, only effective when the zinc is new and clean, but not only does it soon eat away, but its surface soon becomes oxidised, and the action ceases, or even may become reversed. The Cumberland process gets over this difficulty by supplying current through one or more immersed anodes from an external source, so that the polarity is certain and the extent of the action regulable. It is no longer necessary to use zinc, and the anodes are pieces of iron shaped according to the particular vessel, and connected to insulated bolts passing through the body of the casing. The current return is, of course, by the vessel itself. Each anode has an adjustable resistance in series with it, and an ammeter can be switched into any circuit. Current is supplied at from 6 to 10 volts by a small motor generator. It is found that the hydrogen forming on the negative surface of the vessel not only protects it from corrosion, but the mechanical action of the hydrogen given off between the metal and the scale loosens and carries away all dirt, scale, or grease adhering to the metal. If the vessel to be protected is already free from scale, the hydrogen being given off prevents any solids settling or adhering to the surface, and also neutralises any corrosive effect of acids, oils or free oxygen contained in the water. The apparatus can also be arranged to form a low-water alarm, as the current will cease to flow if the anodes are no longer immersed. The system is in use in the United States Navy, where it has been very favourably reported on, and by several large steamship companies, as well as in electric generating stations in New York, Brooklyn, Brussels, Llanelli, in the power-house of the City & South London Railway, and elsewhere.

**Siemens' Cinematograph Films.**—It was a pleasure on Monday afternoon to escape for a short time from the heated, dusty atmosphere of the London streets into the private boxes of the Kingsland Imperial Picture Theatre, where, at the invitation of Messrs. Siemens Bros. Dynamo Works, Ltd., Lamp and Fittings Department (Dalston, N.E.), we witnessed, among others, two excellent films connected with this well-known firm, after having greeted Mr. H. A. Pryor and many of his assistants, who so ably carried out the arrangements. The first film depicted the manufacture of "Wotan" and "Tantalum" lamps, as carried out at Dalston (see ELECTRICAL ENGINEERING, March 20th, p. 164), while the second was of humorous intent. The title is "A Lighter Burden," and the story shows the quarrels of a husband and wife, presumably caused by the bad light in the house, the final notice for payment of the quarterly account comes, and when it is paid no money is left, hence many amusing adventures, as only the cinematograph can show. Returning from the city at night, the "hero" falls asleep in the train, and dreams of marvellous feats of strength and beauty performed by the personages in Messrs. Siemens' posters, who come to life. The result of all this is the purchase of a multitude of "Wotan" and "Tantalum" lamps, whereby peace is again effected in the household, and the electric light bill dwindles. This film is more clever, entertaining and enlightening than many of the so-called ordinary humorous films.

## TELEPHONE TRANSMISSION

A PAPER entitled "Practical Application of Telephone Transmission Calculations," by Mr. A. J. Aldridge, was discussed at a meeting of the Institution of Electrical Engineers on May 30th, immediately following the annual general meeting. The author showed how complex were the analytical equations relating to the propagation of telephone currents, and proceeded to develop a graphical construction for the determination of current distribution. To simplify the working, he had designed a special scale, with a pivoted arm and protractor for the rapid measurement of the vectors in his diagrams. The treatment was based throughout on reference to miles of "standard cable," with "allowances" for the terminal impedance any piece of apparatus in the form of the length of such a cable which give the same reduction in efficiency as the apparatus in question. The magnitude of errors introduced by certain causes was investigated, and the application of the method to various practical problems was dealt with. The apparent equivalents of one or two different kinds of line, both unloaded and loaded, were considered, and the question of "reflection losses" was considered. Arising out of this, the author remarked that at the time the National Telephone Co. and the Post Office agreed as to the standard cable, the reflection effect of the terminal apparatus was not sufficiently appreciated. He discussed briefly the pros and cons of other proposed standards, including Dr. Breisig's attenuation constant and length, Major O'Meara's "centibeta" standard, and M. Devaux Charbonel's *al.*, expressed in terms of 5 mm. aerial wire. Finally, he proposed, as a more suitable standard, a 20 lb. cable, with arbitrary but practical constants, and terminals giving the same impedance as the line (therefore giving no reflection), and fed with an E.M.F. of 5 volts. Proceeding, he discussed composite lines, and showed that quite considerable losses may occur at points in a line where there is a change of impedance not detected by the ordinary methods of working out. The latter part of the Paper contained some experimental results. Oscillograms were given, showing that the voice waves usually consisted roughly of slightly-damped series of oscillations of one frequency, and might, generally speaking, be represented by a very low fundamental of about 160 cycles, and a predominating 5th harmonic of 800 cycles. The strength of the fundamental was of the order of 5 per cent. of the principal harmonic. In case of a woman's voice, although the fundamental was higher, the harmonic was lower than in a man's voice. The result of this was that a single testing frequency of 800 was recommended, and experimental tests were mentioned confirming its suitability.

Other conclusions arrived at by the author were that:—The normally accepted equivalents of uniform lines (*i.e.*, the equivalents calculated on the assumption of an infinite line) may be seriously wrong when applied to practice unless the equated length of the line is of the order of 20 or 25 S.M. This improvement with length, however, is only due to the fact that the terminal loss is then less important with regard to the line loss. The equivalents of heavy gauge open wire lines may be improved by the addition of cables at the ends. The relation between the impedances of the various factors, however, must be taken into account in determining the amount. The terminal apparatus plays a most important part in transmission, the sending instrument no less than the receiving. The present system of making telephonic calculations, *viz.*, by adding together the equated lengths of the various sections of a line, is only approximately correct. To obtain accurate results, the various reflection losses must be added. The overall transmission is the same in either direction over a line composed of two or more differing types, though the distribution of losses is not the same.

## DISCUSSION.

Mr. B. S. COHEN (G.P.O.), in opening the discussion, said that it might be possible to overcome the difficulty of settling the best length of section by an adoption of Professor Pupin's equivalent sine formula applied to the general case of any telephone line. It was known that in the case of loaded lines a spacing giving 7,000 coils passed by the wave in one second gave the best results in practice, and in working out such a case graphically, the length of section would be determined by this figure quite irrespective of the error due to the graphical construction. On the question of the equivalent of a 600-lb. open copper-wire line under various terminal conditions, he drew attention to the value of the equivalent for various cases, which showed that in no case would the transmission of the complete circuit be better when cable was added, and although it had been suggested that under certain conditions the addition of terminal cable to an open-wire trunk line might improve the transmission, he knew of no case in which this

actually took place. In connection with the speech tests, it was necessary to take into account the fact that the line leakage in practice might vary with both the frequency and amplitude of the applied speech wave, the impedance of the terminal instrument changed with frequency and current, and the variation in efficiency of telephonic apparatus with the load. The standard proposed by Mr. Aldridge was to have a terminal instrument of the same impedance as that of the line. This amounted to retaining the existing standard, but always making due allowance for the terminal effects, which in the case of unloaded lines had hitherto been considered negligible. The suggestion that a standard terminal instrument might be constructed having the same value as the line impedance involved an instrument with a negative angle, and the only telephonic apparatus of this nature that could be constructed appeared to be a condenser telephone, which in its present state of evolution was not at all suitable for use as a standard. He would also like to emphasise that it was only possible to make standard cable measurement of loaded lines against unloaded lines when there was negligible reflection effect. We were still waiting for a satisfactory multi-frequency wave which would give accurate standard cable measurements for all conditions of line.

Mr. J. G. HILL (G.P.O.) said that in order to predict the quality of speech, attenuation, impedance and distortion must be taken into account in the circuit, and this the author had not done. Distortion was most important. In the case of a high resistance cable, for instance, a very different result was obtained compared with an open line. In the case of an open line with inductance as well as resistance, the formula was very different, and those accustomed to comparing underground circuits found a tremendous difference in the tone and quality of speech, and this accounted for some of the results of Mr. Aldridge. In any long telephone circuits there were periods at different points of the line, and they very often had a combined effect which was tantamount to a loading effect, and the losses were appreciably less than would be expected, seeing there was a loading effect. It had also to be ascertained whether the constants really were constant, and many experimenters besides himself wished to obtain some confirmation of Mr. Aldridge's results before finally accepting them. There were losses at present unaccounted for. It should not be overlooked that the standards adopted by the G.P.O. were not obtained from any calculations, but from arbitrary experiments, and, therefore, should not be compared with calculations.

Mr. J. E. KINGSBURY referred to the frequencies selected in the Paper, and looked forward to some other harmonic being selected as the result of future experiment and analysis.

Mr. F. GILL (Engineer-in-Chief, National Telephone Co.) said that the standard mile was first used in the United States, and was adopted in this country as something already in existence which would form the basis of an international standard, rather than setting up a standard of our own. He agreed with this action as a wise one. At any rate, he would advise that a change should not be made lightly nor until we were certain from the practical point of view. He did not agree with Dr. Breisig's standard because it did not cover both the line and the instrument.

Mr. H. KINGSBURY said that there were a large number of frequencies above and below 800 which could not be ignored; and speech tests carried out recently demonstrated the fact that a frequency of 800 was not the correct one. In fact, no single frequency gave true results, and as time went on, more attention would have to be paid to the range of frequencies if the question of articulation was to receive the attention it deserved.

Mr. ALDRIDGE, in reply, thought Mr. Cohen's idea with regard to the Pupin formula worth going into, although the question was rather complicated in having to allow for lines of different types. His own suggestion was that his standard should be taken as the basis, and the existing standard be used as a working standard from the other one. He agreed with Mr. Hill that the constants varied, but this could not be allowed for in a formula, although he quite agreed that more information was required about the constants for an ordinary line, and how they varied. The Paper was written more with the idea of giving a simple means of calculation than to give any very precise results. The 800 figure taken and objected to by Mr. H. Kingsbury was admittedly not a strict mean. The present standard was the best one for general purposes, but it was necessary to correct for the terminals at the end, which he had done. He agreed that the standard circuit should include the instrument. The single frequency of 800 appeared to give correct results. It might be that other frequencies would be necessary on open lines, and it was quite possible to make tests with two or three frequencies and to combine the results.

**American Hydro-electric Schemes.**—A Bill was recently passed providing for the immediate expenditure of about £135,000 by the New York State on an hydro-electric scheme, using water from the Barge Canal, and supplying eight municipalities for public purposes and for distribution to private consumers. This is intended to be only a beginning, and if successful the system may be extended.

## CATALOGUES, PAMPHLETS, &c., RECEIVED

**FANS.**—We had occasion last week to refer to the very complete line of electric fans manufactured by the General Electric Co. (57 Queen Victoria Street, E.C.) at the special factory at Witton, Birmingham, and the thoroughness of the inspection and testing of the work as it passes through and out of the shops. We have now before us a copy of the latest catalogue of these fans, which seems to cover the whole field of the application of electricity to ventilating work. The "Freezor" fans, as they are called, range from small desk fans, taking no more than 20 watts, to centrifugal and exhaust fans up to 60 ins. in diameter. The Swan patent cooling fan, which we recently described and illustrated, is included, as well as several patterns of punkah. Special attention should be called to the "Liteweight" 12 in. fan, weighing 10 lbs., and taking 25 watts, to the oscillating fans, and the fans with the new "Pitter" multiple blade. A full range of accessories and spare parts is included.

**AMMETERS AND VOLTMETERS.**—Another new list from the General Electric Co. deals with ammeters and voltmeters of the moving coil type, for continuous currents, arranged in pedestal cases so that they can be attached to controllers and switch boxes.

**SWITCHES, &c.**—A list from Siemens Brothers Dynamo Works, Ltd. (Supplies Department, 38 & 39 Upper Thames Street, E.C.), which is supplementary to their ordinary list of installation accessories, contains particulars of several new lines of switches, among which may be mentioned a porcelain-cased watertight switch for damp situations, a door switch, and a flat pattern of tumbler switch. Another list deals with the chain-pull design of switch lamp-holder, which has already been described in our columns.

*Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."*

**DRIVING CHAINS.**—Hans Renold, Ltd., send us a pamphlet entitled "Driving Chains for Speeding Up," which contains some remarkable results in lowering production costs as a direct result of adopting chain drive in connection with gear-cutting and other machinery. In the case in point a 60 per cent. gain in output was obtained for only 10 per cent. increase in power.

**FANS.**—An exhaustive list of fans for D.C. or A.C. circuits has just been issued by the Electrical Co., Ltd. (122-4 Charing Cross Road, W.C.). The company makes a special feature of a 12-in. swivel and trunnion fan, which it claims to be the best and cheapest on the market. It is finished in matt green with gilt bands and blades, and a three-step regulator is included. The ordinary desk fans and a multitude of designs of ceiling fans as well as shaft and centrifugal ventilators are also listed, and some notes on the use of fans, giving the quantity of air which should be displaced per hour for different buildings, are contained in this publication.

**RUBBER CABLES.**—A sheet from the same firm gives the new prices of 600 megohms S.W.G. rubber cables. Other lists embracing 2,500-megohm cables, flexible cords, steel conduits, and fittings, will also be sent on application.

**MOTORS.**—A leaflet from Krupka & Jacoby, Ltd. (26-36 Chapter Street, Westminster, S.W.), gives prices of A.C. induction motors of 1/10 and 1 h.p. and series commutator motors and D.C. motors for powers between 1/40 and 1/6 h.p.

**FANS.**—The same firm has a new list dealing with its desk, ceiling, and porthole fans. A device is also listed by which an ordinary table fan may be given an oscillating movement, and a special offer of 9-in. D.C. desk fans is being made.

**ARC LAMP SUSPENSION.**—A circular letter from the London Electric Firm (George Street, Croydon) calls attention to the prices of their contact suspension device span-wire lowering gear, which are considerably less than those of equivalent poles.

**ALUMINIUM.**—The British Aluminium Co., Ltd. (109 Queen Victoria Street, E.C.), are issuing a folder for their leaflets. A new sheet illustrates the use of aluminium feeders for electric railways, and a pamphlet deals with the characteristics and advantages of aluminium, and gives some useful information on making bends, joints, &c., while a table has been prepared showing those sections (rod, bar, and strip) which have been found to be most in demand, and are now standardised and quickly obtainable.

**ELECTRIC LIGHT BATHS.**—A new catalogue is to hand from the Dowsing Radiant Heat Co., Ltd. (105 Great Portland Street, W.), of electric light cabinet baths or "Solariums," including patterns recently installed in several large country

houses, portable baths, and special apparatus for local treatment.

**ELECTRICAL APPARATUS FOR MINES.**—A new catalogue from Siemens Brothers and Co., Ltd., describes various electrical appliances for mines. Shaft-signalling apparatus is represented by the Rutherford patent system of luminous signals combined with bells, and an ingenious apparatus for recording bell signals by punching in a paper strip is included in this; the last signal made remains visible by being projected on a screen. Other forms of bell indicator are also included. Another system is by illuminated dial step by step instruments, similar to engine-room telegraphs. A number of forms of gas- and water-tight bells and hooters are dealt with, as well as push buttons, signalling switches, and other accessories, and the latter part of the catalogue treats of mining telephones and exploders. Among the last-mentioned is a particularly compact exploder weighing no more than 1½ lbs.

**RECEIVERS FOR WIRELESS.**—A folder issued by the Sterling Telephone and Electric Co., Ltd. (200 Upper Thames Street, E.C.), mentions the single and double head-gear receiving sets for wireless telegraph operators. The resistance of each receiver is 1,000, 2,000, or 4,000 ohms.

**ELECTRIC HEATERS.**—A variety of designs of heaters with the well-known Schniewindt resistance net elements are illustrated in a new list from the Schniewindt Electric Co. (40 and 41 Stanforth Street, Birmingham). Another pamphlet from the same firm describes a number of varieties of electric hot plates for industrial, domestic, and scientific purposes. Particular attention should be drawn to the asbestos cement hot plates for keeping dishes, &c., hot. Cast-iron boiling plates in a number of sizes are also listed.

**"SCHOLEY'S MAGAZINE."**—A neat little quarterly publication is being issued under this title by Scholey & Co., Ltd. (151 Queen Victoria Street, E.C.), giving technical information as to the extensive lines of electric and engineering material handled by the firm. It is specially addressed to shippers and exporters, who should find it very useful.

## CORRESPONDENCE

### THE ELECTRICAL TRADES BENEVOLENT INSTITUTION.

*To the Editor of ELECTRICAL ENGINEERING.*

SIR,—We are surprised to notice the very poor response to the appeal to subscribe the £1,000 for the Electrical Trades' Benevolent Institution, of which £600 has already been promised, for we quite thought that the few hundreds necessary would have been immediately forthcoming. Possibly, were it made more widely known that donations of £50 would be thankfully accepted to make up the required amount, the difficulty might be overcome. In order to start the ball rolling, we will follow on Mr. Byng's offer to the effect that we will give £50, providing the remaining £400 is made up in amounts of not less than £50 before the time stated at the dinner. As only about a month now remains, may we ask you to make a special appeal on these lines?

We are, sir, yours respectfully,

477-487 Liverpool Road, A. P. LUNDBERG & SONS.  
Islington, N.

June 5th, 1913.

**Electrical Engineering in South America.**—We have received some particulars of some South American electrical enterprises for which Mr. A. O. Kolkhorst has been responsible. Mr. Kolkhorst is coming to England, as announced elsewhere, to practise as a consulting engineer, but was for three years general manager of the Chilean Electric Tramways & Light Co., of Santiago. At the same time he acted as general manager of the Valparaiso Electric Tramways & Light Co. The whole of the electric tramways in Valparaiso, and the lighting and power plants were carried out under his direction and supervision, and he had continuous control of this undertaking from 1903-1912. The supply of electrical energy to Valparaiso is taken from a 6,000 h.p. water power station situated seven miles out of the city, and there is also a 3,300 h.p. steam station in the city. The capital city of Chili, Santiago, draws its supply of electricity from a 20,000 h.p. water power station on the river Maipo. The station is some 14 miles from the city, and the water is taken from the river some 10 miles above the station. There is also a steam power station of 7,000 h.p. in Santiago. The water power plant above-mentioned belongs to the Over Sea Electric Power Co., and was also under Mr. Kolkhorst's management. The capital expenditure on these three undertakings has been about £3,500,000. The companies were very prosperous, and paid good dividends to the shareholders, in spite of the disastrous results of the great earthquake of 1906, and the consequent depreciation of Chilean money, in which all tramway receipts and electric lighting accounts were paid

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as to accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,343.

There are twelve three-core lead and armoured cables suspended in a culvert. Ten are for three-phase current; two are for direct current. I wish to test by some simple method in the culvert, without cutting the cables, to ascertain which are carrying three-phase current and direct current respectively, which are dead and which are alive, but not delivering current. There are no link boxes. The apparatus used must be such that one man can carry it. How can this be done?—R. S.

(Replies must be received not later than first post, June 26th.)

### ANSWERS TO No. 1,341.

A system of discriminating fault protection has been recently developed in which the difference under fault conditions of the currents flowing in two concentric conductors in parallel, and normally equal, is utilised to trip the switch. It is desired to apply this system to three single concentric cables in parallel originally laid for A.C. single-phase distribution, but now required to be converted to three-phase as feeders. What are the objections to this arrangement, and what is the formula for mutual induction of the cores (1) when currents are equal and in the same direction; (2) when one current is larger than the other, but both in the same direction; (3) when one current is in the opposite direction to the other? What would be the effect of a stray field on each core; for instance, how would the voltage induced in the cores compare if a length were suddenly drawn sharply through a magnetic field?—"KINK."

No replies worthy of an award have been received.

L. FOXES suggests, with regard to the replies to Question No. 1,337, published in our issue of June 5th, that in testing the resistance of the armouring of cables by the method described, there is the danger of a break in the armouring being overlooked if the armouring makes good earth on both sides of the break, as, of course, the test gives the parallel resistance of the armouring and the earth shunting it. He also points out that the connection for the insulation test mentioned by "Colliery Electrician" will not include the rotors of the motors, which must be tested independently.

**City and Guilds of London Institute.**—The report of the Council for the year 1912 refers to the second gift of £50,000 by the Goldsmiths' Company towards the extension of the Imperial College (South Kensington), subject to the balance, about £13,000, being added to the endowment fund of the College, and the income being used for higher educational and research work carried on in the new extension, which is known as the Goldsmiths' Company's Extension of the City and Guilds (Engineering) College. The reports show that at this and the Finsbury Technical College the attendances and results have been well maintained. At the latter there is now a third year's course in electrical, mechanical, or civil engineering for those who desire to continue their studies after the two years' certificate course. New apparatus has been added in all departments. At the City and Guilds (Engineering) College there has been marked activity in original research and other special work; particularly was this so in the electrical department, where there were also special courses on electrical machinery, advanced applied electricity, electrical engineering as applied to mining and metallurgy, as well as the railway engineering course.

## THE MODEL WARSHIPS AT EARL'S COURT EXHIBITION

BY this time many of our readers will have witnessed the miniature naval battle which is a feature of the Imperial Services Exhibition at Earl's Court, and it may be of interest to point out that these vessels are worked and controlled electrically. The boats were built and equipped by Bassett-Lowke, Ltd., of Northampton, for those responsible for the display. There are externally scale models  $\frac{1}{2}$ -in. to 1 ft., and vary from 25 ft. in length for the largest battle cruiser to the 12 ft. of the destroyers, and they vary in "tonnage" from 2,740 lb. to 1,560 lb. The correct number and disposition of guns have been fitted, and the larger ones are electrically controlled and trained, and fired by one of the two operators within the vessel. The searchlights and navigation lights are illuminated electrically, and the torpedo nets are automatically operated. The whole fleet consists of four super dreadnoughts, two battle cruisers, two destroyers, and the Royal Yacht. Naturally, the proprietors of the exhibition do not wish full details of the extraordinarily ingenious details of the internal electrical and mechanical devices on the ships to be disclosed, but we may say that the propelling motors are of  $1\frac{1}{2}$  h.p. wound for 50 volts, and are supplied with current from a set of storage batteries carried within the ship, and supplied by the Premier Accumulator Co. The control arrangements consist of an eight-point resistance

PART OF MODEL WARSHIP, SHOWING DECK ARRANGEMENTS.

frame, separate reversing switch, and the usual protection fuses, &c. The batteries are so arranged that the charging leads are brought to a suitable heavy plug situated conveniently on the deck. After each display the ship is simply brought alongside the wharf by the charging boards and suitable leads plugged in. The searchlights are very small, only measuring  $1\frac{1}{2}$  in. diameter, but throw quite a powerful beam, showing up well at a distance of 150 ft. They are supplied at a low voltage, and contain metal filament lamps run at a high efficiency. A parabolic reflector is used in conjunction with suitable lenses to concentrate the beam. All the searchlights on each vessel can be controlled by the afterman, and can be trained, elevated and depressed and switched on and off as desired. It should be mentioned that the fleet was built throughout at Northampton, under personal superintendence of Mr. S. Winteringham, from designs by Mr. E. W. Hobbs, and to the instructions of Capt. R. Raby, Naval expert to the Exhibition.

**Electrical Equipment of the ss. "Imperator."**—The new liner *Imperator*, of the Hamburg-Amerika Line, which has just made her maiden voyage to New York, is one of the largest ships in existence, being 919 ft. in length, with a tonnage of 50,000. Electric power is used to a considerable extent on board, the watertight doors are fitted with electrical as well as hydraulic closing gear, and there are several electric lifts. Searchlights of large size, given as 50,000 c.p., are provided, and the wireless telegraph equipment is said to be the largest on any ship—three operators are on duty night and day. Submarine bell signalling is also provided for, and the gyrostatic compass is used. The main electrical generating plant consists of five 220-kw. turbine-driven, 110-volt machines, and there are upwards of 10,000 lamps on the ship. An emergency generating plant of 110 kw. is provided above the water-line. A completely fitted machine shop is situated in the forward engine-room equipped with electrically-driven lathes, drills, planers, &c.

## "ELECTRICAL ENGINEERING" PATENT RECORD

*(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)*

### Specifications Published June 12th, 1913

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

**3,978/12. Automatic Telephone System.** B. DEGENHARDT. Each subscriber has a contact disc at the exchange which bears two contacts for each subscriber, all the equivalent contacts being in series. The insertion of a contact plug by the calling subscriber releases a lever and causes a current impulse to be delivered to a polarised relay at the exchange, by which the calling subscriber's switch disc is electro-magnetically coupled through a shaft which is common to all the discs. The coupling is maintained only until the calling subscriber's switch disc has been rotated by a step-by-step movement through an angle equivalent to the movement of the lever. Ten figures.

**4,067/12. Telephone Relay System.** S. G. BROWN. Each of the relay terminals is connected to the middle of highly inductive coil situated about the middle of one of the lines connecting two stations. Thus speaking currents operate the relay, and the relay currents on the two parts of the line balance one another, although the receiver is affected. Five figures.

**6,486/12. Wireless Telephony.** W. T. DITCHAM, H. GRINDELL MATTHEWS and GRINDELL MATTHEWS W. T. SYNDICATE. The spark gap electrodes consist of two rods of dissimilar metals with parallel faces and connected to masses of heat-conducting metal. This gap is energised with D.C. through inductive resistances shunted by a condenser, and an inductance which is tightly coupled to an inductance in the antenna circuit through inductances in an intermediate circuit containing the microphone. Notwithstanding the high group frequency of the spark, discharges do not develop into an arc with this connection. Three figures.

**11,559/12. Feeder Protection.** E. G. WATERS. Should one of two parallel cables become faulty it is cut out. To effect this the primaries of two current transformers are connected in the feeder circuits, while the secondaries are connected in opposition through wattmeters or reverse current or power relays operating separate circuit breakers in the respective feeders. In addition two other current transformers with primaries similarly connected and secondaries cross-connected are used, so that normally little choking action is obtained, but on the occurrence of a fault the impedance of the combination is greatly increased, and the power available for cutting out the faulty main is increased. Five figures.

**11,597/12. D.C. Motor Load Equalising.** S. ECKMANN. To reduce current fluctuations due to varying load, some of a series of motors are provided with flywheels. These have an additional series field winding carrying the current supplied to the installation. In addition, automatic regulators vary the motor fields in proportion to the total current, so that the current taken by each motor is caused to decrease when the total current increases and vice versa. Two figures.

**11,714/12. Recording Wireless Messages.** H. MERTON. The telephone receiver of a wireless installation is connected through the medium of a sound intensifier to a phonograph, which may be started and stopped by the messages. Received signals may thus be reproduced when required. Two figures.

**11,957/12. Damping Alternator Oscillations.** SIEMENS-SCHUCKERT. A heavy flywheel is connected to each machine through a spring coupling in which considerable friction is set up by the relative displacements of the parts. Alternatively the frictional resistance due to the movement of a liquid in a restricted part of a vessel rigidly attached to the machine may be used. Two figures.

**12,075/12. Water Heaters and Cookers.** H. S. MARTIN. The substance to be heated is contained in a vessel of quartz or other substance readily permitting the passage of radiant heat. The resistor is arranged on the outside of this vessel, and is in turn protected by a casing not in contact. Insulated handles, or a third wall between which and the second may be an air space, vacuum, or other heat insulator, may be used. Two figures.

**14,091/12. Drying Cables, Conduits, &c.** C. DONDEERS and E. WINTERER. A liquefied gas is allowed to expand in successive stages so that it enters the pressure reducer in a gaseous state and not as a saturated vapour. Carbonic anhydride is suitable. One figure.

**18,908/12. Magazine Arc Lamps.** H. E. ANGOLD. To transfer the feeding catches from one pair of carbons to another in inclined flame lamps where the carbons are fed downwards by shunt coils, energy accumulated by a weight or spring by the descent of the first carbons is expended in bringing the catches back to their starting point. Three figures.

**22,539/12. Switch Indicator.** H. H. BERRY. Iron-clad switches are provided with a reflector controlled by the handle,

so that closing the switch causes it to reflect light, while opening prevents its doing so. Four figures.

**5,872/12. Ordnance Alarm Signals.** KRUPP. For the safety of the gun's crew of guns mounted in turrets, signals are given when danger positions, due to obstruction in the line of fire, arise during traversing, &c. Signal lamps are fed continuously with A.C. through one circuit, and in addition automatically through another with A.C. of a different frequency when the danger arises—whereby flickering results. Four figures.

### Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, E.C., at the price of 8d. each, post free. Summaries of some of the more important of these patents will appear in our next issue.

*Names in italics indicate communicators of inventions from abroad.*

**Arc Lamps:** OFFICINE GALILEO [Searchlights] 12,380/12; PASQUALINI [Searchlights] 13,680/12; B.T.-H. Co. [*G.E. Co., U.S.A.*] [Electrodes] 18,220/12; CROMPTON & Co., 237/13.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** LEITNER [Automatic supply system] 16,174/12; CONNER and HEALEY [Flexible cables] 19,807/12.

**Electrometallurgy and Electrochemistry:** HIORTH [Extracting iron and steel] 16,275/12; ELEKTRIZITÄTWERK LONZA [Obtaining alkali metals from their fused halogen compounds] 3,575/13.

**Heating and Cooking:** MATTHEWS [Heating] 12,330/12; VENNER, 12,569/12.

**Ignition:** LANCHESTER [Engine starters] 12,418/12.

**Incandescent Lamps:** HUBERS (*Julius Pintsch A.G.*) [Drawn tungsten filaments] 5,026/12, 5,027/12, and 5,028/12; [Drawn tungsten alloy filaments] 12,752/12; GLADITZ [Ductile tungsten] 12,244/12; [Tungsten wire drawing] 12,469/12.

**Storage Batteries:** WILSON [Charging] 9,735/12.

**Switchgear, Fuses and Fittings:** NAYLOR and NAYLORGRAPH, LTD. [Lamp-holders] 12,381/12; GIBSON [Terminals and connectors] 12,445/12; PICKARD [Lamp fittings] 29,736/12; WEISS [Fuse plug] 3,732/13.

**Telephony and Telegraphy:** CORWIN [Telephone exchanges] 12,547/12; COLONNA [Polarised telegraphic relay] 18,369/12; GIRARDEAU [Aerials] 24,345/12.

**Traction:** WHITLAKES [Railway cab signalling and automatic control] 12,371/12; TARRANT and SYKES [Railway signalling] 13,125/12.

**Miscellaneous:** MUNDEN and MUIR [Announcers] 14,224/12 and 14,225/12; KITSEE [Synchronous phonographs and kinematographs] 14,880/12; C. & G. MÜLLER SPEISEFETTFABRIK [Metallic catalysts] 23,643/12; DALEN [Light signals for life-buoys] 24,564/12; Goss [Alarm clocks] 26,502/12; TROETEL [Door alarms] 1,323/13; CONIDELON SOC. ANON. [Vanadium catalyst] 5,174/13.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Dynamos and Motors:** ZENK [Commutators] 11,886/13.

**Ignition:** KETTERING [Engine starters] 7,543/13.

**Telephony:** AKT. L. M. ERICSSON [Electric control clocks for trunk line switchboards] 11,658/13.

### Opposition entered to Grant of Patent

**8,040/12. Variable Speed Dynamos.** C. A. VANDERVELL and A. H. MIDOLEY. This specification deals with a variable speed constant pressure dynamo, in which there are two brush sets (the second set short-circuited) per pair of poles and unwound polar projections midway between the wound field magnet poles.

### Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** CALLENDER'S CABLE CO. and J. C. A. WARD [Connecting cables to junction boxes, earth plates, &c.] 5,103/02.

**Dynamos, Motors, and Transformers:** J. S. PECK [Adjustable ratio transformer] 4,357/04; SIEMENS BROS. (*Siemens & Halske*) [Heavy current transformer coils] 4,464/08.

**Electrochemistry:** A. F. and F. A. LINDEMANN [Röntgen ray tube] 4,479/08.

**Telephony and Telegraphy:** A. F. COLLINS [Wireless, using the earth as conductor] 4,691/06; W. FAIRWEATHER (*Brown Hoisting Machinery Co., U.S.A.*), 4,685/07.

**Traction:** H. PIEPER [Electromagnetic engine governor for oil engine-electric set] 4,163/06; W. R. SYKES [Motor operated points: locking and indicating gear] 4,368/08.

**Miscellaneous:** P. SELBACH [Blasting cartridge for use under water] 4,707/07.

## ELECTRIC TRACTION NOTES

The L.C.C. tramway accounts for the year to March 31st show a gross profit of £739,053. Interest and redemption of loans absorbed no less than £730,687, and after making certain other deductions and additions there is a surplus carried to appropriation account of £497. This position is a very much worse one than in the previous twelve months, and in a lengthy report the Highways Committee calls attention to the difficulties under which the tramways work by reason of so many dead ends and the general want of intercommunication throughout the system. Motor omnibus competition is drawn special attention to, especially in connection with the facilities which are afforded to omnibus services by reason of certain street widenings, a portion of which is often paid out of the tramways accounts. The matter was referred to at Tuesday's meeting of the Council, when it was announced that the Highways Committee was taking steps to make the present routes more remunerative by extension and linking up. The large contribution made by the Tramways toward street improvements and maintenance which were taken advantage of by the motor-buses was called attention to, and an amendment by Sir J. Benn alleging bad management of the tramways was lost.

The House of Commons last week voted £1,000,000 to meet the cost of constructing the Post Office tube railway from the east to the west of London. The railway will consist of a 9-ft. tube, and will contain two tracks, upon which will run trucks electrically controlled from a distance.

In their report for March 31st, 1913, already referred to on page 325 of our last issue, the directors of the British Electric Traction Co. refer to arrangements for introducing motor 'buses in connection with their tramways in other parts of the country than in London; to the provision of capital for the Maritime Coal, Railway, and Power Co., Nova Scotia; the formation of the Rio Grandense Light and Power Syndicate with a capital of £100,000; and the purchase of a concession for lighting, tramways, and power in Pelotas (Brazil), where the generating station is under construction. Before declaring the dividends already referred to, £40,000 has been set aside as reserve for depreciation.

The Stoke-on-Trent Corporation, after a lengthy debate, deferred consideration until May, 1915, of a proposal by the Potteries Electric Traction Co. to extend the lease under which the Tramway Company now works. The Estates Committee, which has had the matter under consideration, recommended that the lease be extended to 1927.

At the meeting of the Kalgoorlie Electric Power and Light Co. it was stated that the cost of repairing the damage done to the Company's overhead lighting and traction mains by the cyclone last year was £2,800. This, of course, does not take into account the loss of revenue during the time the tramways were not running.

The first fifteen months' working by the Corporation Tramways in Coventry, show a net profit of £1,440. The General Manager has reported that large sums will have to be incurred on renewals before the expiration of the period for the repayment of the loan for the purchase of the Company's undertaking, and under the circumstances the balance is to be carried to reserve. The actual amount, however, is only £185, as the balance has been appropriated towards the re-laying of a portion of the track, &c. At the commencement of the year, a deficit of £1,000 was anticipated, and this amount is nevertheless to be taken from the rates to help towards meeting the first instalment of the cost of renewals.

The annual accounts of the Leeds Corporation Tramways show a net profit of £61,374 after meeting all charges. This sum has been transferred to relief of rates.

The Board of Trade has sanctioned the running of trailer cars on the L.C.C. Merton circular route.

## TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

The House of Commons Committee which has been inquiring into the Imperial wireless telegraph scheme has issued a report with regard to the investments of Ministers in Marconi shares. The report has already appeared in full in the daily papers, and there is no need for us to give it in our columns. Briefly, however, it may be said that in drafting the report the Committee followed strictly party lines. The report adopted by the vote of the Liberal members of the Committee, who constitute a majority, states that "Sir Rufus Isaacs acted in perfect faith and with a sincere conviction that his personal interests conflicted in no wise with his public duty," and that he and the other Minister concerned "acted throughout in the sincere belief that there was nothing in their action which would in any way conflict with their duty as Ministers of the Crown." The draft report first prepared by the Chairman, Sir Albert Spicer, suggested that Sir Rufus Isaacs's acquisition of rights in the American Marconi Co. was liable to give rise to misconception, and that he would have been well advised to have had nothing to do with it; but Sir Alfred was apparently the only Liberal member who desired to express even this mild form of censure. The Conservative members of the Committee all voted for a draft report prepared by Lord Robert Cecil, which stated that Sir Rufus Isaacs, Mr. Lloyd George, and Lord Murray acted "with grave impropriety" in their purchase of the American Marconi shares, and that the persistence of rumours and suspicions had been largely due to their reticence as to these transactions, which was "a grave error of judgment."—Yesterday's *Punch*, referring to the criticisms of the report in the Conservative papers, says that one side makes party capital out of Marconi's, and the other side invests party capital in Marconi's.

At the annual meeting of the Marconi Wireless Telegraph Co. of America on Tuesday considerable growth of business was reported, and a profit of over \$200,000 was declared. A 2 per cent. dividend was declared.

Owing to the extreme dryness of the climate at Freemantle, Australia, in the new wireless station which has just opened communication with Sydney, a distance of 200 miles, an insulated counterpoise is used. This consists of about 100 insulated cables radiating from the antenna tower, joined and supported by three concentric circles of wire.

The Newfoundland Government proposes to extend its sea-board telegraph system by some 250 miles during the present season, says the *Electrical Review* and *Western Electrician* (Chicago), and to build three more wireless stations in Labrador, and to establish a telephone system for St. Johns and a number of the outlying places.—Damage estimated at about £2,000 was done by fire to the wireless station at Cape Race on the night of May 5th. The fire was started by a spark from the sending apparatus, and the wooden buildings were destroyed, but the aerial tower was not damaged.

The *Electrical Review* and *Western Electrician* (Chicago) says that after stringent tests it is understood that the improved Poulsen system of wireless telegraphy, as developed by the Federal Telegraph Co. of California, has been adopted for linking up Washington with the stations at Hawaii, Guam, the Philippines, and the Panama Canal zone.

The line between Tangier and Arzila was repaired on the 12th inst. Private telegrams are being sent by this route, but they are subject to delay, and must be accepted at sender's risk.—The routes via Kanbure and Raheng were down and telegrams for Siam were being sent via Madras-Saigon.—On the 14th inst. one line was restored, and the other on the 16th.—The Martinique-Paramaribo cable was restored on the 14th inst., but there is still another section to be put through before the Hayti route to Brazil, &c., is in order. Since the 17th inst. telegrams to Turkey have no longer been subject to delay, and they are accepted without sender's risk.

## FARADAY HOUSE.

ESTABLISHED 1889.

(Proprietors: The SYNDICATE OF ELECTRICAL ENGINEERS, Ltd.)

WHEN CORRESPONDING WITH ADVERTISERS, PLEASE MENTION "ELECTRICAL ENGINEERING."

## LOCAL NOTES

**Bedworth: Street Lighting.**—The contract for street lighting has been given to the Leicestershire & Warwickshire Electric Supply Co., whose price is reported to be 5s. per lamp cheaper than that of the local gas company.

**Bradford: Electricity Profits.**—There was a net profit of £8,477 on the electricity undertaking last year, from which £7,736 has been transferred to relief of rates.

**Brighton: Electricity Accounts.**—The electricity accounts show a net profit of £1,406 for the year to March 31st, against £8,450 for the previous twelve months. In his report Mr. J. Christie, the Borough Electrical Engineer and Manager, calls attention to the fact that the rates and taxes for the year increased by £1,231, and that an average of 2s. 9½d. per ton more has had to be paid for coal, which is equivalent to an increase of £2,133. During the year substantial developments have been made in connection with the application of electricity to cooking, two fairly large installations having already been fixed, and numerous inquiries for smaller outfits suitable for domestic service are being received. In order to provide an adequate stock of appliances, Mr. Christie strongly recommends that a substantial sum for this purpose be included in their next application to the Local Government Board for further capital for other works. The amount of coal used per unit sold has been still further reduced, and inclusive of all transmission, transformer and distribution losses, is now 4'18 lbs., as against 5'26 lbs. in the previous year. Considerable controversy is going on in Brighton as to allocating all or any portion of the year's profits to relief of rates, but Mr. Christie advises the Committee against doing this.

**Bristol: Electricity Accounts.**—The accounts of the Electric Lighting Department for the year to March 25th show a gross profit of £56,536, and after meeting interest and capital charges, adjustment of income tax, and depreciation of stores, there is a balance of £6,889 to be added to the balance from last account of £4,397. From this has been deducted certain sums in respect of wages of permanent workmen engaged on capital work, new meters, &c., and after transferring £6,000 to general reserve, a balance of £2,411 is carried forward.

**Dudley: Sale of Electricity Undertaking.**—All the difficulties concerning the sale of the electricity undertaking to a private company have now been overcome.

**Eastbourne: Electricity Accounts.**—Mr. J. K. Brydges, the Borough Electrical Engineer, received many congratulations at the last meeting of the Corporation on the successful results of the past year's working of the electricity undertaking. The net profit for the year was £2,495, which is £1,406 more than in the previous twelve months. Of the capital expenditure of £200,000, no less than £101,590 has been repaid.

**Ilford: Electric Lighting Accounts.**—The net profit on the electricity undertaking last year was £1,602, which has been added to the reserve account, which now amounts to £10,520. An extract is quoted in the Electricity Committee's report, from a statement by the Local Government Board auditor, who refers to a proposal by a member of the council who attended at the public audit, that the auditor should express an opinion with regard to the supply of power to the Tramways Department, as it was alleged that the present price is unprofitable. The auditor, however, held the view that it was not his duty to interfere on points of policy, and the general administration of local authorities' trading departments.

**Kingstown: Electric Lighting.**—The New Kingstown Electric Lighting Co. is pushing forward its arrangements for dealing with the electric lighting Order which has been granted by the Board of Trade. The Company's Engineer, Mr. W. Tatlow, has inspected several sites for a power house.

**Leeds: Strike of Municipal Employees.**—Having regard to the somewhat exaggerated statements which have appeared in the local Press relating to the strike of Leeds Municipal employees as it affected the Electric Lighting Department, we are able to state that although the Gas Workers' and General Labourers' Union called upon all its members employed by the Corporation, and the call was fairly generally responded to, it only caused a suspension of cable-laying for a few days. A number of members of the Union engaged inside the generating station also ceased work, but their places were readily filled, and no occasion was given for a moment's anxiety as to the maintenance of the supply.

**Limerick: Legal Action re Electricity Deficit.**—A decision

has been given by the Limerick County Court Judge with regard to the position of the local electric lighting undertaking. The loss on the undertaking up to date has been £15,000, and Mr. Michael O'Brien, a member of the Corporation, appealed against the levying of a rate to meet the deficit upon the undertaking on the ground that under the Corporation's electric lighting order the maximum price was fixed at 8d., but that the price charged was only 5d. per unit. It was pointed out that although there are 7,000 ratepayers in Limerick, only 267 use electric light, and that if the charge for electricity was increased from 5d. to 7d. per unit the undertaking would be a commercial success. Mr. E. B. Thornhill, the Borough Electrical Engineer, expressed the opinion that an increase in the price would tend to a decreased consumption. The Judge decided, however, that the Corporation has outstepped the limits of its provisional order when it levied a 5d. rate to make good the deficit on the electric lighting undertaking. He held that they were not entitled to do this, and he quashed the rate.

**Manchester: Rateable Value System of Charging.**—Under the new rateable value system of charging for electricity which has been adopted by the Electricity Committee (see ELECTRICAL ENGINEERING, June 12th, page 343), occupiers of houses not exceeding £30 rateable value will have to instal and use heating and cooking appliances requiring two kilowatts of maximum demand; houses over £30 and under £50 three kilowatts, and houses over £50 four kilowatts.

**Newport (Mon.): Fire at Electricity Works.**—Considerable damage was done on Friday to one of the older turbo-generators by a fire, which originated in a short circuit in the stator windings of the machine.

**Plymouth: Increase in Price of Coal.**—The Electricity Committee has accepted a tender for the supply of 8,500 tons of coal at 18s. 10½d. per ton. The existing contract price is 14s. 6d. per ton.

**Warrington: Electricity Accounts.**—There was a net profit of £2,944 on the working of the electricity undertaking for last year. The Borough Electrical Engineer states that a traction battery and reversible booster are about to be installed in order to provide for more spare plant. He also calls attention to the fact that generating plant extensions are necessary, and that as soon as the most suitable type of plant is settled upon this should be put in hand as soon as possible.

**West Ham: New Domestic Tariff.**—We regret that in the reference to the new tariffs for lighting and heating in our last issue there was an error in the heating tariff. This should have read: For heating and cooking the annual charge is 10s. per kilowatt for the first two kilowatts and 6s. 8d. for each additional kilowatt. After the first kilowatt the charges are subject to division into tenths, i.e., 1s. and 8d. per 100 watts for apparatus on the 10s. and 6s. 8d. rates respectively.

**Worcester: Electricity Accounts.**—Although the electricity accounts show a deficit of £1,526, they include a sum of £2,167, which has been charged to revenue, although it is largely of a capital nature. When the new machinery recently installed at the Hylton Road Station gets into full operation, it is anticipated that the result at the end of the present year will be very satisfactory.

**Yarmouth: Electricity Profits.**—After meeting capital charges, a sum of £427 has been added to appropriation account from the profits of the electricity undertaking last year. The Electricity Committee has resolved to transfer £744 from this account to the fund for capital expenditure, for which loans are not obtainable, and in addition to allocate £4,000 from the reserve fund to this account.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

Generating Stations, Sub-Stations, Mains, &c.

**Limerick.**—Switchboard, 1,000 ampere-hour battery, motor-driven booster, balancer, &c. Borough Electrical Engineer, July 3rd.

FOR  
STEAM JOINTS  
USE

JOHN HUDSON & CO.'S SUCCESSORS, Mansell St., London, E.

**London: Stepney.**—Two E.H.T. converting plants suitable for 6,000-volt three-phase A.C. to low-tension D.C. (See an advertisement on another page.)

**Southwark.**—Extensions at the Penrose Street power house.

**Woolwich.**—A loan of £3,230 has been sanctioned for the purposes of the electricity undertaking.

**Newcastle-under-Lyme.**—Paper and lead feeder cable, vulcanised bitumen distributor cables. Town Clerk, June 21st.

**Nova Scotia.**—A Steel and Coal Co. will shortly open a new mine in Nova Scotia to be worked electrically. Further particulars from the Board of Trade Intelligence Department.

**Walsall.**—Application is to be made for sanction to borrow £3,000 for prospective expenditure on mains.

**Waterford.**—Mr. Mark Ruddle, Chief Engineer to the Dublin Corporation, has reported favourably upon an electric lighting scheme for this district.

### Wiring

*The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.*

**Aberdeen.**—New theatre. London & Provincial Theatres Co.

**Bradford.**—New music hall.

**Bristol.**—Large warehouses at Bristol Docks.

**Dartmouth.**—New schools.

**Greenock.**—Alterations and additions to post office. H.M. Office of Works, London.

**Leyton.**—Electric lighting of school, Church Road. Architect, W. Jacques, 2 Fen Court, Fenchurch Street, E.C.

**Lichfield.**—New Union Offices. R. J. Barnes, architect.

**Manchester.**—North Manchester secondary school.

**Motherwell.**—New high school.

**Paisley.**—New school.

**Penzance.**—New school.

**Rugby.**—Workhouse. Consulting Engineer, Mr. T. S. Shenton.

**South Shields.**—Electric lighting at Barnes Council School. Borough Electrical Engineer.

**Wimbledon.**—New Town Hall.

### Miscellaneous

**Brighton.**—Overhead equipment for railless traction system. Tramways Engineer, June 23rd.

**London: Woolwich.**—A loan of £1,000 has been sanctioned for the purchase of electrical fittings to be supplied under the Council's free wiring powers.

## TENDERS RECEIVED AND ACCEPTED

**Swindon.**—The tender of the Brush Electrical Engineering Co. for a 500-kw. turbo-generator with condensing plant has been accepted at £5,567.

**Walsall.**—The tender of the British Westinghouse Co. for a 100-kw. rotary-converter has been accepted at £636.

## APPOINTMENTS AND PERSONAL NOTES

The West Ham Corporation invite applications for the position of Tramways Manager at a salary of £550, rising to £700 per annum.

Messrs. F. Gill and W. W. Cook, of the National Telephone Co., who are now practising as consulting engineers, have taken offices at Winchester House, Old Broad Street, where they will have associated with them, amongst others, Messrs. D. B. Fulton, H. Green, S. H. Pook, E. Williams, and J. H. H. Boyd, all of the National Telephone Co.

Mr. R. W. Weekes is taking into partnership Mr. A. O. Kolkhorst, who has had considerable engineering experience in South America, and the firm will practise under the title of Weekes & Kolkhorst, at Maxwell House, Arundel Street, Strand, W.C.

The members of the Metropolitan Association of Electric Tramways Managers are entertaining Mr. H. E. Blain to dinner on Friday, July 4th, at the Municipal and County

Club, Whitehall, on his resignation as Tramways Manager at West Ham, and also as Chairman of the Association.

Mr. C. M. Davis, Commercial Power Engineer in the Bristol Electricity Department, having been appointed to a similar post at Hampstead, Mr. T. R. Stancombe, of York, has been appointed to fill the vacancy at a commencing salary of £160, rising to £200 per annum.

Mr. G. P. Farrer has been appointed Assistant Engineer in the Brighouse undertaking.

Mr. H. S. E. Webster has been appointed Assistant Mains Engineer at Dover.

Plumber joiner required for E.H.T. cables. (See an advertisement on another page.)

Shift engineers with experience in high-tension work are required. (See advertisements this week.)

An improver is required for three-phase power station substation work. (See advertisement on another page.)

A junior engineer is required for three-phase rotary substation and distribution work. (See advertisement on another page.)

## MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. G. Smith and Sons, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £69 to £69 10s. (Last week, £69 5s. to £69 15s.)

**Branch Office.**—British Insulated and Helsby Cables, Ltd. (Prescot), have removed their Manchester branch office to more commodious premises at Orme Buildings, Parsonage. Telephone and telegraphic addresses as before.

**Paraffin and Gas Electric Sets.**—The Electrical Engineering & Equipment Co., Ltd. (109-111 New Oxford Street, W.C.), are taking up the sale of the well-known "Pelapone" oil and gas engines.

**Works Outing.**—The annual outing of the employees of the Siemens "Wotan" and "Tantalum" Lamp Works, Tyssen Street, Dalston, was held on Saturday last, the 14th inst., when a party of over 500 made a journey to Ramsgate. A special train left London Bridge at 7.15 a.m., and after enjoying a day of fine weather returned about 11 p.m.

**Change of Address.**—The Bastian Electric Heating Syndicate, Ltd., are moving their sales office next Saturday from 91 Palmerston House to 185 Wardour Street.

**Change of Address.**—Messrs. Nalder, Brothers & Thompson, Ltd., 34 Queen Street, E.C., will be shortly moving their factory and head office to larger premises at 97A Dalston Lane, N.E. They will retain an office and showroom in Queen Street, and their existing part machine shops at Kingsland Green will be continued as before.

## COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

**Electrical and General Investment.**—A gross profit of £14,797 is announced, of which £5,268 remains after meeting interest and other charges, together with the £2,726 brought forward from last year. £3,072 is to be carried to contingencies fund, and a further dividend of 1s. per ordinary share, and 6d. per deferred share, is recommended, with £2,922 carried forward.

**Aron Electricity Meter.**—A dividend of 7 per cent. for the year is declared.

**Marconi International Marine Communication Co.**—The accounts for the past year show a net profit of £24,400 after deducting £10,700 for depreciation. A 10 per cent. dividend is recommended.

**MARRYAT & PLACE**  
**DYNAMO & MOTOR HOSPITAL,**  
 28, MATTON G<sup>W</sup>  
 LONDON, E.C.

## EIGHTEENTH ANNUAL CONVENTION OF THE INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION

IN our last issue we published a report of last week's proceedings up to Tuesday night. On Wednesday the meeting was held in camera, to discuss the I.M.E.A. Bill and Electric Cooking, and in the evening the Annual Dinner was held. On Tuesday afternoon visits had been paid to the Deptford and West Ham electricity works, and on Wednesday Lot's Road power house was visited.

### ANNUAL DINNER

The first toast on the list, after the loyal toasts, was that of "The Houses of Parliament," to which Sir William Howell Davies, M.P., who has done so much in connection with the I.M.E.A. Bill, was to have replied. He was, however, unable to get away from the House of Commons, and the toast was omitted.

Mr. W. Duddell, F.R.S., in proposing "The Incorporated Municipal Electrical Association," emphasised the necessity of all electrical engineers to pull together for the common good. One advantage of conventions such as these was that it tended to the development of a broadness of view amongst the members which was of the greatest possible good for the industry generally.

The PRESIDENT, in replying, said that although the Association was a young one, having had an existence of only 18 years, it could claim to have done some good work. The Association also was unique in that although primarily a technical institution, it was composed both of engineers and Chairmen of Committees, a happy combination which he thought had had much to do with its success. The Association had a membership of about 400, composed equally of engineers and chairmen, but although small the membership represented a capital outlay in the hands of municipalities of about 120 millions sterling. Referring to the absence of Sir William Howell Davies, the Member of Parliament for Bristol (South), and the work he had done for the Association in connection with the I.M.E.A. Bill, Mr. Edgcome remarked that he did not know what the Association would have done without Bristol, for, in addition to what had been done by Sir William Howell Davies, the engineer at Bristol was the Association's esteemed, hard-working, and energetic Honorary Secretary, one of their past-presidents, and certainly one of the ablest men among them. Then Alderman Pearson, Chairman of the Bristol Electricity Committee, was Honorary Solicitor to the Association, and all the members were familiar with the work he also had done for the Association. In connection with the I.M.E.A. Bill (ELECTRICAL ENGINEERING, June 12th, p. 343), he said it seemed illogical that some municipalities should have these powers and others should be refused them, but if they showed a united front perhaps they would be able to get the measure passed, although, as they knew, there was opposition to it. There was a great deal of difficulty at present in getting any private Bill passed, but perhaps later on it might be put through as a Government measure if it were really seen that the Bill was wanted by the bulk of the electrical industry. Mr. Cave, the Member for Kingston-on-Thames, had promised his help in the matter, and he urged upon the members of the Association to do all they could to get their own Members of Parliament to assist in the same way. Hitherto the efforts which the Association had made to get the members to interest their Members of Parliament had borne very little fruit. But let them keep putting the matter before their Members of Parliament, and everything should be done to secure a big support outside the House also. A resolution passed at the meeting that morning would also assist them in getting the Bill through.

"The Past Presidents," coupled with the names of Messrs. Wordingham, Rider, and Snell, was next proposed by Mr. R. A. Chattock (Vice-President), and all three in response spoke of the affection which they still had for the Association, and the pride they felt in the important position which it now occupies.

The toast of "Our Guests" was proposed by Mr. H. Richardson (Vice-President), Councillor C. H. Burge, F.I.C. (Mayor of Kingston), and Dr. Ferranti replied.

On Thursday, members proceeded to Kingston by special train, and met in the Empire Theatre, where they were welcomed by the Mayor.

A Paper on "Air Filtration" was then read and discussed.

### AIR FILTRATION, COOLING AND VENTILATION OF ELECTRICAL MACHINERY

By J. CHRISTIE (*Engineer and Manager, Corporation Electricity Department, Brighton.*)

LARGE steam turbo-driven alternators, such as it is common practice to instal in modern power houses, are now supplied by leading manufacturers under the most stringent guarantees as regards steam consumption, coupled with reliability and liberal overload ratings; in fact, within limits, the only condition governing the outputs obtainable from them is the temperature rise which the insulation can safely withstand. Till a few years ago such machines were run with open ends and natural ventilation, but the temperature rise, even on less than full load, was often excessive. By fitting end bells, air ducts and forced ventilation, the makers have with the same carcass been able to double the output with a decreased temperature rise, whilst the selling price per k.w. of rating has been proportionately reduced. All this has proved a great boon to the purchaser, but the advantages thus gained have brought in their train a host of minor though still serious difficulties in the way of filtration and conditioning of the air, which so far have only been dealt with in a rather crude fashion by means of cloth screens.

To cool large units of plants effectively with the surrounding air at normal temperature, some 5 to 7½ cub. ft. of air per min. per kw. of rated output must be forced through the windings of the machine. The general practice is to draw this from outside the building, or, where the conditions are favourable, from the engine-room basement. The circulation is effected either by separate motor-driven fans or by fans fitted to the rotating part of the machine itself. For moderate-sized units of, say, 3,000 to 5,000 kw. at speeds of 1,500 r.p.m., the author favours this latter arrangement, as being cheaper, more efficient and reliable; but for large slower-speed plants and where there are several of these sets working together, he considers that undoubtedly the best lay-out is to provide main inlet and outlet ducts, common to all machines, with branches and dampers to each unit, and to have a combination of fans on the rotors themselves supplemented by separate motor-driven fans for heavy overloads, the air filters being fitted at the ends of the intake duct and preferably in a suitable chamber outside the building.

All air about a power house is heavily charged with dust and fine gritty particles in suspension, and unless it is carefully filtered the windings become coated and the air ducts choked up, and, with the consequent rise in temperature, the efficiency of the machine rapidly falls. A sensitive air gauge is a most useful accessory to fix on the main air duct to the machine.

When no filters are provided, the varnish and insulating fabric on the end windings are in time made porous by the heat and the constant sandblast action; and if a machine in this condition is allowed to cool down in a humid atmosphere, the insulation, due to the absorption of moisture, rapidly falls below a safe figure. This, in the author's opinion, is the real cause of many mysterious "burn-outs." Such failures have generally occurred when a machine has just been run up and put on load after a lengthy rest.

The type of air filter most commonly in use consists of closely woven cloth, tightly stretched on wooden or wicker-work frames, and so arranged as to present a large area to the incoming air, thus keeping the velocity and pressure on the fabric at this point as low as possible. The general practice is to allow 2 sq. ft. of filter medium per cub. ft. of air per min. This is approximately equivalent to 1 sq. ft. of area per kw. of rated output, and in the case of large machines it becomes a most unwieldy surface to handle efficiently. At best, this type of filter can only be regarded as an unsatisfactory makeshift, and it possesses the following disadvantages:

- (1) The large space occupied in proportion to its capacity.
- (2) It requires cleaning at frequent intervals.
- (3) The filter cloths wear out quickly and are expensive to renew. (£75 to £100 per annum for cloth and labour is by no means an outside figure for the efficient maintenance of such a filter on, say, a 3,000 kw. set.)

- (4) The cleaning of the filter is a long and dirty job, and can hardly be accomplished without taking the machine out of service for some considerable time.
- (5) Owing to its combustible nature it is a hazardous fire risk.
- (6) Unless of liberal area it quickly chokes up, and the air pressure rises till the fabric bursts. It is well to note that the air pressure on the intake duct of a machine should not be allowed to exceed one to one and a quarter inches of water, otherwise there is a grave risk of oil vapour being drawn in from the bearings if the oil is run at the excessively high temperature one usually sees on turbine installations, and this has a most harmful effect on the insulation.

As an efficient substitute for a cloth filter, a suggestion was put to the author last year to use a water-spray screen such as is fitted in the "air conditioning chamber" in the Plenum system of ventilating large buildings, and facilities were afforded him for inspecting such an equipment in connection with a large institution in London. On the face of it, at first sight, it strikes one as a rather daring proposition to pass air through water then directly into the internal anatomy of a high-tension alternator, but the author was so satisfied with the experiments which he was enabled to carry out that he had no hesitation in recommending his Council to purchase a suitable apparatus of this type for the last new alternator installed at our Southwick Power-house. It consists (see illustration) of a strong rectangular

at Southwick is often enough), wash out the tank with a hose pipe, fill up and start the pump again. All this can be done in a few minutes and without even taking the machine off load.

- (4) No costly filter cloths to frequently wash and renew.
- (5) The resistance to the air is always constant, and is less than one-third that of a cloth filter, so that the power for driving the main fan is proportionately less, whilst the total energy consumed by the outfit as a whole shows a substantial saving over that required by a cloth filter, after making a full allowance for driving the water circulating pump.
- (6) The air after passing through the filter is not only pure, but is generally several degrees colder than the surrounding air, due to its being reduced to wet-bulb temperature, consequently its cooling effect on the machine, volume for volume of air, is proportionately greater, this difference in temperature being generally most marked in the summer time, just when the extra cooling effect is of the greatest value. In tropical climates or in situations where the surrounding air is at an abnormally high temperature, it is possible, by introducing a small refrigerating plant into the water circulating system, to "super-cool" and control the temperature of the air down to a degree far below the corresponding wet-bulb temperature. Experiments which I have carried out show that it is

GENERAL ARRANGEMENT OF AIR-WASHING AND CONDITIONING PLANT OF No. 5 TURBO-ALTERNATOR.  
BRIGHTON CORPORATION POWER HOUSE, SOUTHWICK.

galvanised sheet iron chamber, one end (the air intake) being open and fitted with louvres. This opening is of such sectional area that the velocity of air at this point when the machine is going full blast is comparatively low. The filter is fixed in the basement adjacent to the machine foundations. Some 2 ft. inside the air inlet a water screen is fitted. This consists of a series of small nozzles pitched 6 ins. apart uniformly over the entire area. Some 6 ft. beyond the screen a moisture eliminator is fixed. (This is a sort of baffle, very similar to that used in an oil separator such as is fitted in the exhaust steam pipe between the low-pressure cylinder of a reciprocating engine and the condenser.) Thence the air passes directly into the alternator.

The base of the chamber forms a fresh-water tank holding some 300 gallons, and is fitted with a ball cock off the town mains to keep the level constant and to make up for any evaporation. A small motor-driven centrifugal pump about 2 h.p. circulates this water at a pressure of 20 to 25 lbs. per sq. in. through the system. The nozzles project this water in the form of a finely atomised spray directly against the incoming air (this space, when the apparatus is working, having the appearance of a dense steamy bank of cloud), and all solid matter in suspension in the air is caught and precipitated in the tank. Any beads of moisture or grit carried through with the air are effectively trapped by the eliminator, and nothing but pure cool humid air is carried into the machine. In some localities during the winter months with this class of filter it will be desirable to fit a small steam coil in the water tank, just sufficient to keep the water from freezing.

The advantages claimed for the water-screen filter are :-

- (1) For equal capacity the space occupied is less, and in the case of larger machines only about half that of a cloth filter.
- (2) No fire risk.
- (3) The apparatus is quickly and easily cleaned, it being only necessary to drain off the water at intervals depending on the amount of dirt in the air (once every two weeks

possible by this means to reduce the temperature of the air to within a few degrees of the temperature of the water through which it is passed.

The first cost of a water-screen filter, of course, varies with the size of the alternator to which it is fixed. In machines of, say, up to 3,000 kw., it is some 60 per cent. greater than a cloth filter, but in the case of larger machines of 5,000 kw. and upwards the advantage as regards price lies with the water-screen type.

In the author's opinion, due to the increased cooling effect obtained, especially during hot weather, an extra 10 to 15 per cent. overload can be carried on any machine so equipped without increasing the temperature rise, and if a super-cooling refrigerator is fitted in the water system, this overload capacity can be still further increased to 25 or 30 per cent.; in fact, I firmly believe that in the near future turbines of ample power to carry extra heavy overloads will always be provided. The attendant will then simply load up the alternators to which they are coupled till their temperature attains a predetermined maximum safe limit, and electrically-controlled thermometers or the switchboard for this purpose will supersede the ampere and watt meters now used. This extra cooling effect is perhaps the chief advantage of this system, especially where large units of plant are concerned, as the additional outputs obtainable for practically the same capital outlay amply justifies its general adoption.

The conditions of service under which the Southwick machine operates is generating three-phase alternating current, 50 periods, at 8,000 volts with 250 volts excitation on the field windings. The equipment was, the author believes, the first to be installed in this country, and has been running since August last entirely satisfactorily. The insulation resistance has been consistently maintained, showing that any moisture carried through with the air is harmlessly evaporated on the warm windings of the machine, and that this type of filter may with safety be used for ventilating extra high-tension machines or air-cooled trans-

# STURTEVANT WATER-SPRAY AIR FILTERS

FOR CLEANING and COOLING AIR SUPPLY TO  
ELECTRIC GENERATORS, TRANSFORMERS, etc.

STURTEVANT SYSTEM  
PATENTED.

STURTEVANT ENGINEERING CO., LTD.,  
147, Queen Victoria Street, LONDON.

formers without detriment in any way to their insulation. The additional humidity in the air really has a beneficial effect on the insulation, preventing it from being baked to destruction, as is not uncommon where machines are run at high temperature and heavy overloads with dry, hot, gritty air constantly circulating through their ventilating ducts.

Several engineers who have extensive installations of cooling towers in close proximity to their ordinary cloth air filter intakes have furnished the author with the percentage of humidity in the air as now used. This is often found to be as high as 90 to 100 per cent., so that they are really working almost under the same conditions with their present filters as regards risk, if any, to the insulation due to humidity, but without the cooling and cleansing advantages of the water screen.

With the gigantic units of plant, 10,000 kw. and upwards, now being installed by many of the principal undertakings throughout the country, this system of water-screen filter seems to offer, so far as present knowledge goes, the most satisfactory solution of this somewhat difficult problem of suitably conditioning the air to be used for their effective ventilation.

#### DISCUSSION.

Mr. J. CHRISTIE, before the discussion was formally opened, asked manufacturers who took part in it to give their views on the minimum insulation resistance which they considered safe for alternators of 10,000 volts.

Mr. K. O. HALE (Sturtevant Engineering Co.) said he had been a strong advocate for a long time of the principle of the water-spray system of filtering, but could at first not convince electrical engineers of its advantages. The time arrived, however, when he got Dr. Ferranti to place the first order, and since then Mr. Christie had employed it. He was more than convinced now, after 4 or 5 years' experience with it, that the system must take the place of all cloth filters. The makers of the system guaranteed to put air into the generator entirely free from entrained moisture, and Nature had not given that guarantee in the past.

Mr. D. BENNETT (Balcke and Co.) referred to the Paper as a rather one-sided comparison between the two types of filters. The wet filter had certain advantages over the cloth type of filter, but they were by no means so overwhelming as might appear from the statements made in the paper. It was true that there were no cloths to clean and renew, but the parts in a wet filter which would wear out first would probably be the separating baffles at the air outlet end. They were subject to a current of air which would have a certain amount of moisture in it, and there was undoubted risk of serious pitting after a short time. This might be guarded against by special painting at regular intervals. He would like to know whether any signs of corrosion had been noticed in the filter at Brighton. No figures had been given to substantiate the claim that the resistance to the air was less than one-third that of a cloth filter. The extra overload which it was claimed could be obtained when a wet filter was used appeared on the high side, but no doubt such increased loads could be obtained if a refrigerating plant was employed to cool the air down to a sufficiently low temperature. Such a plant, however, would introduce considerable complications, and must also have an appreciable effect on the first cost and the running cost. Wet filters for large duties—say 5,000 kw. and upwards—would occupy less ground space than dry filters designed for an initial pressure resistance of 1 mm. water gauge, but the dimensions would be very slightly less than those of filters designed for an initial pressure resistance of 3 mm. water gauge. In industrial cities, such as Leeds or Manchester, it had been found necessary to clean dry filters only six or eight times a year, whilst wet filters in similar situations would require to be cleaned once or twice a week; even in such a favourable situation as Brighton it had been found necessary to clean the filter once a fortnight. With reasonable care, cloth filter pockets would last quite two years. The estimate of £75 to £100 for cloth and labour required to maintain such a filter was much too high. A filter for a 3,000-kw. turbo-generator designed for an initial pressure resistance of 1 mm. water gauge would have 60 pockets divided into four sections of 15, or two sections of 30 pockets. With the most modern type of construction the whole of the pockets could be changed and cleaned by two men in about 12 hours at a labour cost of, say, £8 per annum. The work could be done in a much shorter time if a complete set of spare pockets was available. The cost of this would be £33, and as they would last two years, the annual cost would be, say, £16 10s. The total cost of maintaining a 3,000-kw. filter in good condition, therefore, was only £24 10s. It was advisable to shut the machine down for cleaning, but even if only one spare section of pockets was available this time could be very short. The most convenient method of cleaning the pockets was by a vacuum cleaner connected to a condenser or air pump. The fire risk was very little greater than with a wet-type filter, for the timber and cloth could be impregnated to render it flameproof. Mr. Christie must have had an exceedingly cheap filter if the cloth burst whilst in use, or else the plant must have been kept in service until pressure resistance reached a very high figure. The area of cloths as suggested by Mr. Christie was sufficient to ensure that the initial pressure resistance did not exceed about 1 mm. water gauge. In a recent

instance a filter was started up with a pressure resistance of 1 mm., and after running for six weeks night and day, without stopping at all, the resistance rose to only 5 mm., when the first section of pockets was changed. Mr. Christie had said that the maximum pressure should not exceed 1.25 in., and it would be interesting to know what pressure resistance had to be overcome by the air passing through the filter at Brighton. He had at the meeting a small model filter which had been designed to overcome the objections and disadvantages found to exist in earlier designs, and felt sure that this filter in no way merited Mr. Christie's epithet of "crude." The filter was built in sections, having any number up to 30 single pockets per section, and one pocket and frame weighed about 14 lbs. One complete section was controlled, adjusted, or released by operating only four bolts, which were accessible from the outside of the filter casing. Finally, he asked if there was not serious risk in the wet filter of excessive moisture reaching the generator by way of the filter when plant was shut down, which would settle on windings and possibly cause a breakdown when the generator was next started up.

Mr. R. J. KAULA (Willans & Robinson) said that the point to be watched in the use of these air-filters appeared to be the temperature of the air. So long as this, when it left the generator, was well in excess of the temperature entering, the air was quite capable of absorbing any moisture which might be carried past the moisture eliminators; but if the generator was running light, and the heating of the air was very small, there was probably some danger from moisture. He would suggest that it might be advisable, on shutting down, to turn off the sprays so as to pass dry air through the generator and absorb any deposited moisture. Mr. Kaula also pointed out that the danger of a burn-out in one coil of the machine spreading to others was largely augmented by the forced ventilation, and he therefore considered that it was of the utmost importance to provide dampers which could be quickly operated both on the inlet and outlet of the air, so as to shut off the air-current immediately a breakdown occurred.

Mr. S. E. FEDDEN (Chief Electrical Engineer, Sheffield) referred to certain signs of incredulity when he had remarked in that building a few years ago (when he had been one of the first to go in for turbines on a large scale), that his oil costs were 0.004d., whilst the ordinary oil costs were about 0.2d., or something like that. The Paper to-day, however, proved that what he said then was absolutely right. Very little, he continued, was known about the ventilation of alternators, either by fans on the rotors or by independent fans. He had a case of an 8,500-kw. alternator with its own fan, which had to take a load up to 12,000 kw. when used with an external fan. Without the latter it drew a suction of  $\frac{1}{2}$  in., and when the machine was shut down and the motor-driven fan was pumping in air into it, there was an air-pressure of 2 in. Further, when the machine was running with the external fan in use, the suction of  $\frac{1}{2}$  in. was converted into a pressure of  $\frac{1}{2}$  in., so that it seemed as if the external fan had to annul the suction in some way before any useful work could be got out of it. He had the same effect with the balanced draught. On the boilers the makers put a forced draught in, as well as an induced draught, in order to get a balanced draught, and they had absolutely to double the size of the motor on the induced draught before they could get any good effect at all. It was a point worth considering. Mr. Christie said that there must never be more than 14-in. pressure, but surely the greater the pressure in the alternator, the better the cooling effect. The liability to a burn-out after a machine had not been in use for a considerable time existed whether they had the dry filter or the wet filter. He would like to ask manufacturers why they refused absolutely to guarantee their machines if this wet filter was put on. At what voltage did they allow this filter to be put on, and why? It seemed to him that the air from the wet filter, if it was properly regulated, was very little wetter than the air on an ordinary wet foggy day, and the advantages to be derived from it were very great.

Mr. A. H. SEABROOK (Chief Electrical Engineer, Marylebone) said that when he first heard of these filters from Mr. Christie, he asked the contractors for the two 3,000-kw. 6,000-v. alternators of the Oerlikon type, which had been ordered by his Committee, to instal wet filters, but they would not hear of it, and said that, as they had quoted for dry filters, he would have to have them. He asked them, however, to go into the question closely with their designers in Zurich, which they did, and he afterwards took their London man down to Brighton to see the machine running. When they got into the train at Victoria their representative said that there really was no need to go down, because he was quite converted, and had, in fact, ordered eight wet filters and cancelled the order for eight filters of the other type. On the Continent this question of wet filters did not seem to be known at all, and once again the Municipal Electrical Association had been in the forefront.

Mr. F. H. CLOUGH (B.T.H. Co.) said that he had not had much experience with wet filters, but he had seen Mr. Christie's installation. It was working very satisfactorily, and, as far as could be seen, there was no free moisture entering the generator at all. Recently manufacturers had been striving to

prevent dynamos catching fire when a short-circuit occurred, and for that purpose they had introduced mica and asbestos very largely into the insulation. These materials were not so water-resisting as some of the varnishes used previously, and it would be necessary, when wet filters were introduced, to see that an ample amount of varnish was put on all parts, especially just on the outside, and if this were done there should be no doubt that this type of filter would work quite satisfactorily. He certainly thought that they had a great many advantages over cloth filters, and it would be interesting to hear what cloth-users had to say with regard to their experiences. The question was practically as to what insulation resistance should be allowed. A rough working formula was

voltage  
capacity of plant (kw.) + 1,000  
megohms. The insulation resistance was not an entire guide, but he did not think it should drop below this.

Mr. D. FELDMAN (A.E.G. Co.) thought it was not quite fair to call the cloth filter, which had served its purpose very well up to now, a crude method of cleaning air and an unsatisfactory makeshift. There had certainly been very little experience with washing air by means of the spray filter, and he thought manufacturers could be excused for hesitating to adopt the new system hurriedly. Cloth filters were very simple and very easy to clean. Manufacturers could not be asked to accept these spray filters straight away, because they would naturally hesitate to pass the air through water and then send this moisture into the generator, especially when starting up. He could quite understand the utility of the spray filter in cases like Deptford, where it was necessary to clean the air, where the space was limited, and where they had a warm generator, i.e., where the generator and the turbine were not equal as to their full-load capacity. Of course, it was also possible to use a refrigerating plant with a cloth filter. It seemed to him rather complicated to have a number of pipes and a tank which would require painting or regalvanising in the course of time. The man who attended to the turbine would also have to go down several times during the day to see to the motor and starter, whereas with the cloth filter he need not go down at all. The experience of the firm which he represented showed that it was not advisable to have two fans in series, as seemed to be suggested in the paper. The idea seemed to be to increase the volume of air through the machines when the set was running at overload by passing the air from one of the fans on to the other fan on the rotor. In his firm's experience this has not been worth while. A very interesting remark was made in the paper as to the future switchboard with thermometers calibrated in amperes; but it seemed to him that there would be a considerable time lag between the indications of the thermometer and the load on the generator when starting up, as the temperature of the machine would not rise very rapidly. It would take six or seven hours before the temperature was permanent at full load, and a similar time lag would occur when taking the load off.

Mr. J. SHEPHERD (Electrical Engineer, L.C.C. Tramways) said that in connection with certain large extensions for the Greenwich power house of the L.C.C. tramways, it became necessary to consider what to do with the air, whether to use the cloth or the spray system. In common with most engineers, he had not favoured the idea of passing wet air into the generator, and he turned it down at first. But he went to Brighton, and saw the apparatus there was perfectly satisfactory, and it was now his opinion that this was the only way to filter air for generators. With a generator of 1,000 kw. capacity running at 1,500 r.p.m., they had to deal with plant of very small size for its output and occupying only about 1,000 cubic feet, and as this plant would lose anything from 400 to 500 kw. it was obvious that this energy could not be dissipated unless an enormous amount of air was passed through it, and air passing through small passages must obviously be cleaned and cooled. The best way to do this was by passing it through a washing stream of water. The £300 or £400 which the filter might cost did not matter when it was being put upon a plant costing £30,000, especially when it was considered that with very cool air passing through a stream of water there was a gain of 10 to 15 per cent. in the output. His opinion, that the wet filter was the best, was shared by Mr. Fell, his chief, and as a result he was purchasing a plant capable of filtering 100,000 cubic feet of air per min. It was, he believed, the largest plant of this description which has yet been ordered in this country. He had been disappointed at not hearing any data as regards the amount of dirt to be dealt with in these large generators. He had made tests at Greenwich, which was not a dirty station as regards air, although perhaps not so clean as that at Brighton, and had found that the 10,000-kw. machine had to deal, in the normal number of hours in the year, with something like 100 lbs. of fine impalpable dirt, which occupied a space of not less than 10 cubic feet. Obviously, if this were allowed to go into the machine, it would soon choke up the air passages.

Dr. S. Z. DE FERRANTI thought there had been a certain amount of misconception underlying the idea of air washing for cooling generators. It was not a question of wet air. With regard to the nature of the air going through, they might take a lesson from the Taylor-White air compressor which was being installed in some places in the United States,

and more largely in Canada. If they had a river with a small fall, they sunk a very deep well adjoining it, and water was allowed to fall down the well and rise again by another shaft to a lower part of the river, below a dam, for example. With proper air entraining nozzles, the water coming down the shaft took air with it, and the air was separated at the bottom shaft, the water passing out to the lower reaches of the river, and compressed air being delivered as the product of this operation. Although it had been compressed in a mass of water, the air was perfectly dry. Air compressed ordinarily by a piston compressor and then used in an engine gave considerable trouble in the way of freezing when its temperature dropped on expansion, but the trouble was not experienced with the air compressed by this water method. The moral was very simple. If they wished to get rid of the infinitesimal small particles of moisture in the air which was called dampness, put that air into intimate contact with a big mass of water, which would hold the small particles of moisture. In the apparatus described by Mr. Christie, the essential feature was the screen, where the air left to go to the alternator. That screen was a form of baffle, and an essential feature of that baffle was to have it continually wetted by a considerable amount of down-flowing water. Once these principles were fully realised, the system ought to be accepted with confidence for ordinary working. Years ago large alternators and electric machines generally were built with a few large cooling spaces between the iron round about the conductors. They were, however, very weighty, and, consequently, too costly. One of the few good things that the lowest tender idea had done was to make designers reduce all the air spaces very much in dimensions, and put a much larger number of them in. Then came the trouble of these spaces silting up to such an extent that they became a danger, as it was never found possible to clean really properly the very hot places. He agreed with everything that had been said against the cloth filter, and he was only interested and surprised to see from the discussion that morning what good arguments could be brought forward to support a bad end. He had had a cloth filter on a 1,500-kw. machine, which took fire and very nearly caused the burning down of the station. It was hard to call them crude and unsatisfactory, because a lot of skill had been exercised in making them workable, but, nevertheless, they were a makeshift sort of contrivance, which could not be expected to endure. Even the first machine of the washer type that had been installed was eminently satisfactory. He had had one of these wet filters on a machine since last September, and it had been no trouble whatever. No cleaning had been necessary, and the thing went along working continuously night and day, generating about 70,000 units a day. There had been cold weather since the machine had been at work, but there had been no freezing; they opened the windows of the air-washing chamber when the weather was warm, and when the weather was very cold they opened the door into the engine-room to admit comparatively warm air. What Mr. Christie had said with regard to increasing the output of the generator was perfectly right.

Mr. C. H. WORDINGHAM (Chief Electrical Engineer to the Admiralty) said it seemed to him that even if the air was fairly moist there was very little danger of it being deposited on the warm machine. He apprehended that they would not turn on the ventilation until the machine was fairly well loaded up and warm. Dealing with Mr. Christie's remark as to the future switchboard containing thermometers and no other instruments, he thought there was a great deal to be said for it, and it did not seem to him to be any drawback that there was a lag between the rise of temperature and the load, so long as the insulating materials on the machine did not attain a temperature at which they became damaged. The chief difficulty was to know how and where to measure the temperature of a machine, so as to get the maximum temperature.

Mr. T. ROLES (Chief Electrical Engineer, Bradford) said that at Bradford he had cloth filters to deal with air going into three 3,000-kw. turbo-alternators, and they go so dirty that on an average they had to be replaced after one month's use at most seasons of the year. During the dry weather the cloths could be removed and the dust taken from them by beating or with a vacuum cleaner, but in the winter months, when the usual air turned through the filter in Bradford had a humidity of something between 90 and 95, the cloths got coated with what could almost be called a slime, and it was practically impossible to do anything but scrap them. One of the speakers in the discussion had stated that cloth filters were simple and easy to clean; he should like him to try some of the Bradford cloths. The same gentleman also said that trouble might be anticipated with the water-filter by reason of the galvanised iron rusting. Galvanised iron was generally used for building purposes to keep out the rain, and it was also well known that if galvanised iron was kept continually wet, there was less rusting effect than if it were alternately wet and dry. Mr. Roles also traversed the suggestion made by the same speaker that there would be trouble in looking after the pump motor. They had circulating pumps driven by motors, and if a pump with motors from  $\frac{1}{2}$  h.p. to 3 h.p. gave all that trouble, he would be very much surprised. As a result of the use of the cloth filters at Bradford—they had now been in use for twelve

months, and were the best thing he could get at the time—he was strongly of the opinion that it would pay his Committee to take the £300 to £500 that they cost and to replace them with a water filter. He added that he had discovered, both by putting some cotton-wool in the air duct and by passing his hand over the internal windings of the generator, that even after the air had passed through the cloth filter it was not clean. The cotton-wool was quite choked after two or three days, and his hand was blackened. There was no doubt that the heavy portions of the dirt were taken up by the cloth, but the smaller impalpable dust was forced through the interstices of the cloth and got into the machine.

Alderman FRED SMITH (Chairman, Liverpool Electricity Committee) asked if anyone could furnish him with information as to whether it was a scientific fact that air agitated by a fan was purified in an inhabited, hermetically sealed chamber. He believed that an experiment of this sort had been carried out.

Mr. EDGECOME hoped that Ald. Smith did not suggest that this should be tried on the Council.

Mr. J. CHRISTIE, in replying, said, after an experience of ten months, he would not have any other type of filter in his station. His previous cloth filter had been an endless source of trouble and expense to maintain, and it was also a very serious fire risk in his opinion. With regard to pressure, he was quite satisfied that the resistance to the air due to the spray was practically negligible, whereas with a cloth screen it started at about half an inch after the thing had been closed, and in four or five weeks it was up to  $1\frac{1}{2}$  inches. His suggestion for using a thermometer for gauging the load on the machines he hit upon when he visited Mr. Fedden's station, where there was a switchboard with a great number of push-buttons, by pushing which it was possible to get a record of the temperature of everything in the station from the feed-water to the flue gases, and it seemed to him that an extra push-button would not hurt. On the basis of Mr. Clough's formula for calculating for a minimum resistance, it would work out in his own case to be something like three megohms, but he never got his insulation resistance below 15 to 20 megohms, and it kept quite steady. When he first started the filter it was on an old machine newly wound, and the insulation was rather low. He dried it out, and before putting it on load it came to about 12 megohms. After about ten days this gradually rose to 44 megohms, and it remained at that. He then cleaned it and put it on load with the water spray, and the curve fell from 44 megohms to 18, and had remained within three or four megohms of this ever since. The answer to Alderman Smith's question was in the negative.

The following Paper was then read:

## ELECTRIC AUTOMOBILES

By W. H. L. WATSON and R. J. MITCHELL.

THE authors commenced by calling attention to the unco-ordinate state of the electric vehicle industry in Europe, and said that even in America it was but lately that a professional brotherhood of electric automobile engineers, the Electric Vehicle Association of America, has come to pass.

In America some forty companies are engaged in the manufacture of cars, and there are some 20,000 cars of value exceeding twelve million pounds in use. The funds of the Association are largely subscribed to by electric supply companies. British engineers might do well to follow this lead where roads were better, labour costs about half, and electrical energy far cheaper.

There are more than 130 separate models now on the American market, including industrial vehicles, ranging from 500 to 10,000 lb. capacity, and a few particulars of the weights of chassis and speeds for the different carrying capacities are included in the Paper. American practice inclines to the two- or three-tonner for heavy haulage—using the lighter types of vehicles for services where very cheap ton mileage is of no account. From a comparison of the running costs of different sized cars it is seen that a ton-mile by the light delivery van costs rather more than five times as much as the same duty performed by the five-tonner. Speed is purely a question of battery power and motor rating, and as a compromise it is found most economical to make the commercial electric a moderate speed vehicle able to maintain a uniform speed for a reasonable distance varying from thirty-five to seventy-five miles per single charge. Moderate and uniform speed means decreased wear and tear on all parts of the chassis and tyres, which latter are usually guaranteed an extra 20 per cent. in mileage for use on battery cars. The "electric" scores as a sure hill climber largely because of the property of the series motor in that its torque increases almost proportionally to the fall in speed, giving the necessary "drawbar pull" when it is most wanted. As a pure speed machine the electric is admittedly quite

unlikely to compete successfully with present-day petrol automobiles, but it can accelerate more quickly than many other vehicles. On a test made recently in London, a six-ton battery 'bus showed an acceleration of 4.5 ft. per sec. per sec. on the level—a figure 40 per cent. in excess of the average value applying to London omnibuses.

### TRACTION ACCUMULATORS.

The only two types of storage battery in present-day use are the lead sulphuric acid cell and the nickel iron alkali cell, of which the Edison is the best-known example. The modern lead vehicle battery is a compromise between lightness and durability. The usual plan is to make positive plates a little over  $\frac{1}{8}$ -in. thick and negatives somewhat thinner. The pasted type of plate finds most favour, though in some cases a specially light Planté plate has given good results, in spite of the greater weight. Spacing is arranged to be the minimum that considerations of electrolyte volume permit, whilst the specific gravity of the electrolyte is sometimes as high as 1.3. Separators of perforated sheet ebonite or specially impregnated thin wood sheets are used in preference to celluloid. A sealed-in case is nowadays employed, the top being liquid-tight yet removable. As regards their life, there are some instances where such accumulators have given six or seven thousand miles of running before becoming too much reduced in capacity for further economical service. A company running private cars in London reckons to get three thousand miles' life from positive plates, whilst negatives last sometimes as long as six thousand. The modern lead battery in average cases can store a watt-hour for every cubic inch occupied. This means that 2-h.p. hours can be delivered at the road wheels for each cubic foot of battery weighing on an average from 180 to 200 lb.

### THE EDISON BATTERY.

The central idea of Edison's work appears to have been the elimination of sulphuric acid and the substitution of a mechanically strong material in place of lead. After years of experimenting, an alkaline cadmium-copper oxide cell was patented, but was afterwards superseded by the iron nickel oxide cell of 1908. The qualities which have distinguished this cell derive themselves almost entirely from the fact that it is impossible to dislodge active material from this design of plate.

Briefly, the method of loading the active material consists of filling a small perforated steel tube in a series of thin layers, alternatively of nickel hydrate and metallic nickel in a finely-flaked form. The function of the nickel is to improve the rather poor conductance of nickel hydrate. Each tube is made from a thin strip of steel coiled around in a spiral of 0.25 in. diameter,

FIG. 1.—DETAILS OF EDISON CELL.

with the edges lapped over to prevent re-opening, and further reinforced by eight steel bands. A complete positive element is composed of two rows, each of 15 loaded tubes, assembled in a stamped frame of nickel steel, the complete unit having a depolarising capacity of some 40 ampere hours. The negative plate is of a form employed originally for both electrodes. Finely divided iron oxide, incorporated with a small proportion of mercury in order to reduce specific resistance, is loaded into rectangular pockets made of very thin nickel steel strip finely perforated. Each pocket is assembled in a light steel retaining

case and subjected to heavy die pressure, which has the three-fold effect: (1) internally consolidating the active substance; (2) superficially corrugating the faces of the pockets, thus making them elastic yet rigid; and (3) swaging over the edges of the pockets so as to associate them effectively and permanently with the steel frame, making it impossible for vibration or shock to impair the conductivity of the assemblage, and therefore its mechanical unity. A welded steel case replaces the more usually employed ebonite box. This latter material is used in fine strips for insulating purposes between adjacent plates, and to prevent metallic contact between the plates and the case. A feature of the electrolyte, a 21 per cent. solution of potassic hydrate, containing also lithium hydrate, lies in its preservative action on steel—hence terminal corrosion is impossible. The general construction is seen from Fig. 1.

Tests have shown remarkable power of withstanding mechanical shock and over-charging, and the cell is particularly well adapted to services where charges can be effected only in an irregular manner, and in this connection the curves in Figs. 2 and 3, reproduced from the Paper, are of interest. Data of the various sizes of cells made,

FIG. 2.—NORMAL CHARGE AND DISCHARGE CURVES OF EDISON CELL.

from 150 to 450 ampere-hours, show that the volume characteristic of the cell is 0.85 cub. ft. per k.w.h. of available output, corresponding to an average weight of 75 lb. The battery is now guaranteed by its makers to show an undiminished output at the end of four years' all day service in traction work. In use it slowly appreciates in output, and it is no uncommon experience for a battery rated normally at 150 a.h. to give 180 a.h. in everyday service. Very high rate charging is permissible, and has not any detrimental effects if not carried on to an excessive degree. Thus in emergency it is quite undetrimental to charge at five times normal rate for thirty minutes, although normal rate charging is more efficient than high rate "boosting," it is nevertheless exceedingly convenient under some conditions to be able to

FIG. 3.—CURVES SHOWING DISCHARGE OBTAINABLE BY SUPPLEMENTARY NORMAL CHARGE WITH A SHORT DOUBLE RATE BOOST.

charge by the "boosting" method. There are several other storage cells using an alkaline electrolyte now being tested in various parts of Europe. None of these appear, however, to have been employed in electric automobile service, though doubtless the future may bring other steel cells into prominence.

#### CONTROLLERS, CONTROLLING SYSTEMS, &c.

In the case of the lead battery there are objections to discharging portions of the battery in parallel sometimes instead of in series for control purposes, as this treatment may cause injurious sulphating, and a not uniform behaviour of the cells as a whole. The objection, however, has no weight in the case of nickel-iron cells of the Edison type. From the efficiency standpoint the series-parallel method of control is in advance of the systems using resistances which have displaced it, and future practice might reinstate the system with considerable advantage if mechanical difficulties be overcome. Modern vehicle motor controllers are mostly of the continuous torque drum type, operated by a lever, geared up by meshing with a small spur pinion on the drum shaft. Usually a series of five or six speeds is provided—the highest being that obtainable with full battery voltage

across the motor, together with a field partially shunted by a resistance of the iron-grid type. As a rule the controller handle is operated in a horizontal plane underneath the steering-wheel, a press-button being incorporated on the end of the handle to actuate an electric warning signal. Other refinements include the automatic breaking of the current when putting on the emergency brake, which latter, particularly on commercial vehicles, is interlocked with the controller. Yet another modification employs solenoid contactors of the railway type to operate the controller. Electric breaking does not appear to find favour in American practice. Charging plugs were the occasion of much confusion and waste of time in the earlier days of the American industry. This matter should, in the opinion of the authors, be discussed in England as early as possible by those interested. Much trouble afterwards would be saved by the adoption of a soundly designed plug right from the beginning of the movement. Some notes then follow in the Paper on lighting arrangements for electric cars, and the use of ampere-hour meters for revealing the state of the battery.

#### TRANSMISSION.

The simplest of all transmissions is that employed in the Cedes motor wheel, which has done useful work for ambulance and fire brigade work in London. The motors are of the distributed-field multipolar type. They are completely closed against water and dust. There are several so-called wheel-drives to the credit of American designers. Of these the Walker gear uses a single motor to drive two wheels, the actual drive being transmitted by an epicyclic gear running in oil. In the Commercial Car each wheel has a separate motor transmitting its torque through a double reduction epicyclic gear to an internally cut ring similar to the Walker. In the Couple-Gear motor wheel, each wheel encloses a motor, the shaft of which engages by means of small bevel pinions with two parallel bevel rings, one pinion with one ring, the other with the second ring. An advantage of wheel-drive lies in its being possible to apply front or four-wheel drive. Double chain drive is at present almost universal on commercial vehicles, the first reduction being effected by a silent chain of the inverted tooth type. Final drive is usually by unenclosed roller chain. A tendency for light transmission is shown in the Commercial light rear axle, a totally enclosed worm-driven rear axle and motor in one unit. Among pleasure cars few retain the chain drive, but only one uses worm gear. In some cases the first reduction is by silent chain. One, the Church-Field, employs a planetary gear on the transmission shaft, the low speed being geared down. No two makers' systems are alike, and this applies to Europe as well as America.

#### GENERAL FEATURES.

The impression that electric cars must necessarily be ugly is dispelled by the first Arrol-Johnson-Edison *coupé* designed in collaboration with Mr. J. F. Monnot, which has recently been undergoing trials. Regarding the weights of commercial cars, being essentially moderate speed machines it should be possible to make them slightly lighter than their petrol competitors, particularly in the case of the heavy type of passenger machine. The somewhat heavy design adopted by American manufacturers may be due to the bad roads. It is likely that the roads of the United Kingdom may permit of a lighter design. The most usual position for the battery is amidships and longitudinal. In one or two cases the battery is mounted in two trays, one on each side of the chassis, which can be pulled out sideways on castors, the side lid of the battery-box serving, when hinged down, as a horizontal platform for this purpose. It is not usual to make provision for unshipping the battery in place of a "freshly charged" renewal. Practice favours rather the method of giving a vehicle a battery adequate to deal with an average day's work.

#### ELECTRIC VEHICLE MOTORS.

The series motor is employed in automobile work almost exclusively, its high starting torque constituting a practical advantage that so far has offset the defects of momentarily heavy copper losses and consequently reduced efficiency during acceleration periods. Experiments have been made with compound wound motors, and with regenerative making systems, but there seems little likelihood of such systems finding favour with the lighter types of vehicle, although for heavier work the possibilities are more hopeful. There is considerable variation in the methods adopted by American manufacturers for rating their motors. The authors suggest that a rational method of rating vehicle motors would be to define normal rating as that b.h.p. output required on a hard

level rolled dry road with vehicle full loaded—this figure being taken as an average for, say, a mile journey each way, after the car had done an hour's work fully loaded on an undulating road. The index of overload capacity should then be expressed as a percentage measure of the current value allowable for thirty minutes as compared with normal current. On an average the best practice inclines to motor speeds of 800 to 1,000 r.p.m. The desirability of enclosing a vehicle motor makes the temperature difficulty greater, and it is suggested that some attempts at internal ventilation might be practicable in spite of dust troubles. The usual construction of these machines favours a carcass of cast-steel, generally of the four-pole type. Considering the extra cost of making the field carcass from laminations would be hardly more than 15 per cent., and that a reduction in weight of 25 per cent. is claimed for this method of construction, there appears to be an opening for improvement in such a direction. From characteristic curves it can be seen that a motor taking 50 amperes at 80 volts can be operated over a range of from 2 h.p. to 11 h.p. without the efficiency falling off below 80 per cent. A steep torque-current curve is also obtained. In the "J.L." machine a radical departure in design is made. In place of solid salient poles the field frame is built up from laminated multi-polar stampings somewhat like an armature turned inside out. The field windings are of strip form and are connected in a continuous series forming a closed circuit like an armature winding. A saving in weight of 80 per cent. is stated to be possible, as compared with the results attained using average construction.

#### THE C.M.B. AND THOMAS SYSTEMS.

The main object of the system developed by Messrs Macfarlane & Burge, as applied to battery traction, is to employ electrical means of limiting the maximum discharge of the battery to some predetermined rate. The system in which the now well-known C.M.B. converter is employed to supply a variable voltage to the driving motor was fully described in Messrs. Macfarlane & Burge's recent Paper before the Institution of Electrical Engineers (see *ELECTRICAL ENGINEERING*, Feb. 29th, 1912, p. 101). The control is entirely by small rheostats in the excitation circuits, and regenerative making is obtainable. In traffic work as much as 17 per cent. of the energy can be restored to the battery by this means, and very low consumption of current has been recorded.

As is well known, the Thomas Transmission system was originally evolved with the idea of making available an infinitely variable speed torque gear change, and as such is used in conjunction with petrol engines on road and rail vehicles (see *ELECTRICAL ENGINEERING*, May 4th, 1911, p. 236, and Nov. 7th, 1912, p. 627). In this system an epicyclic gear always in mesh is used in conjunction with two electric machines, and the power is transmitted partly mechanically and partly electrically in proportions depending on the excitation. In the modification for battery-driven cars, a shunt motor would displace the engine, and would be started up light, and regulation and control of the speed of the car effected by the Thomas gear only. The component machines would be coupled up as shown in Fig. 4. The total addition

FIG. 4.—THOMAS TRANSMISSION AS APPLIED TO BATTERY VEHICLES.

to the weight of the mechanical equipment would be approximately equal to the weight of a single motor required in the direct case, and the extra cost approximately equal to the cost of such a motor. The extra weight of the equipment is stated to be balanced by the saving possible in battery weight.

#### A FRONT DRIVE SYSTEM.

The "F.R.A.M." front-driven traction was specially mentioned on account of its ingenuity, and a  $3\frac{1}{2}$ -ton vehicle was described. In this the whole of the mechanism is mounted on a truck which is pivoted vertically so that the two wheels may turn nearly at right angles to their normal direction. Steering is effected entirely by electrical means—namely, by accelerating one motor above the speed of the other, thus causing the whole vehicle to turn towards the faster wheel. Breaking is by regenerative control. The back part of the

vehicle is easily interchangeable; thus, for municipal purposes the same tractor can readily be converted into a water-cart, dust-cart, or waggon. The vehicle can be turned almost in its own length. The usual battery equipment is a lead-type 80-volt, 40-cell accumulator weighing about 18 cwt., and giving an output of 240 ampere-hours. On some recent tests in London a distance of thirty-one miles was accomplished on one charge, including stopping hundreds of times and restarting. Current consumption is about 1 unit output per mile. These machines are used considerably in Paris for municipal purposes. They can be had with either lead or Edison batteries.

#### THE PLEASURE AUTOMOBILE.

While the authors considered that the greatest results in the future would be achieved by the commercial vehicle, they had a few words to say regarding the private passenger car, and that there was a class of user who would welcome the "reliable, noiseless, clean, stateliness" of the electric automobile. In America they were much appreciated by ladies, and the lady owner-driver was common. Arrangements have been made for the manufacture of twelve hundred pleasure car electrics—all propelled by the Edison battery—in the works of Messrs. Arrol-Johnstone at Paisley. In the opinion of the authors there is a very wide field indeed for the pleasure electric, on account of reliability, simplicity, silence, and absence of odours, absence of "stand-by" losses, comfort and cheapness of operation.

#### RUNNING COSTS.

It appears from tests by the Massachusetts Institute of Technology that under American conditions the electric is from 15 per cent. to 25 per cent. cheaper to run than the petrol truck—this in spite of the fact that American users pay 8d. per gallon for fuel against our 1s. 9d.—and that in the U.S.A. electricity is hardly ever supplied at less than 2d. per unit, whilst it often costs 3d. The Paper concluded with a number of tables of running costs of commercial vehicles with lead batteries in America, varying from 882 d. per mile for a 700 lb. van to 23'65d. per mile for a 10,000 lb. lorry. The authors were of opinion, however, that a vehicle of the last-mentioned size with an Edison battery could be run in England at 13'82d. per mile if charging current were available at 0'5d. per unit.

#### DISCUSSION.

Mr. A. H. SEABROOK (Chief Electrical Engineer, Marylebone) said that it seemed that the user must decide whether to pay a good price for the battery and a small annual maintenance charge, or a small price for the battery and a high annual maintenance charge. This was the main difference which everyone who was going to use these vehicles would have to consider as between the lead and the Edison types of battery. For some reason which he was unable to explain, we were absolutely behind every civilised country on the question of self-contained electrically-propelled vehicles. It was not because of roads: ours were as good, and better, than those of other countries, and the price of current compared well with any other country in the world. He was inclined to think that it had something to do with the attitude of the British battery makers, who either condemned electrical vehicles altogether or damned them with faint praise. Electrically-propelled vehicles should appeal to municipalities particularly more than to the private user. Mr. Christie, of Brighton, had been making interesting experiments, and there was a possibility of sweeping the whole of the horse traction out of the municipal service there. Some useful tests had been made recently in his own district with the F.R.A.M. vehicle, referred to in the Paper. This was the only electric vehicle of which he had had actual experience as to cost. It was a French machine, and it had been put at the service of the Public Health Service Department of Marylebone for some months, and it had been running for seven or eight days for various purposes. They loaded it up to  $1\frac{1}{2}$  tons, and ran it out on what they called a slopping round and a dust-collection round, and also street-sweeping round. The dust collection, of course, involved stopping about 1,400 times a day. For the sweeping it had to hold a makeshift arrangement of a couple of horse-drawn brooms. These were very difficult conditions, the starting and stopping, and the weight and pull of the brooms. But in spite of that, throughout the whole tests, the units put into the machine were less than one unit per mile run, and the efficiency of the battery, motors, and gear was approximately 65 per cent. With regard to tariffs, there was no necessity, as there was in the case of electric cooking, to make a very low rate. He asked members of the Association who were considering what to charge to take into consideration the price they could get. It would be quite ridiculous to offer an all-round competitive price of  $\frac{1}{2}$ d. per unit for electric vehicles, because in his opinion the value of the service was about one penny for very large commercial purposes. A firm running 50 cars, of course, would come in under special con-

tract; but he did not believe that even the Authors would say that an all-round usual price of one penny to 1½d. per unit would have any effect as regards restricting the use of these vehicles. There was still an urgent necessity for encouraging the use of electricity for all purposes. His own district was largely a lighting district, and his lighting revenue was a class of business he had to keep a very close watch upon. For instance, during the last twelve months the introduction of the new 16-c.p. metal filament lamp had dropped his revenue considerably more than £7,000, so that he was keenly on the lookout for all other uses of electricity.

Mr. W. W. LACKIE (Chief Electrical Engineer, Glasgow) said that in November last year the Glasgow Corporation ordered an electrically-propelled commercial vehicle, which was delivered in February of this year. It was sent to Glasgow by rail, and the man who was sent to the station to get it, and who had never seen the vehicle before, drove it away without any trouble whatever. It cost £650, weighed 33 cwt. empty, and carried a load of one ton. With one charge it ran from 37 to 40 miles, and had done this regularly for four months, during which period it had run from 550 to 600 miles at a cost per mile of 0.6d. This compared with 1.2d. for a similar petrol car at a time when petrol was very much cheaper than it was to-day, so that there was no occasion to sell electricity under 1d. per unit for charging at the present price of petrol. He was warned that this electric car would not climb hills, but it had been up hills in Glasgow that no horsed vehicle would think of going up. They previously had horse vans, which cost £14 each per month to run, but the cost of running this electric car and allowing 20 per cent. depreciation was £19 per month; but it should be pointed out that this car was doing the work of two vans, so that the Corporation was well in pocket over it. Another strong point about the vehicle was that it could be used on Sundays at night for special jobs for which the horse vans could not be got out. The charging of the battery could be done at other times than peak-load times. The cost of working the vehicle at 1d. per unit worked out to £26 per annum, which was equivalent to three domestic consumers.

Mr. J. CHRISTIE (Chief Electrical Engineer, Brighton), like Mr. Seabrook, was losing revenue due to the introduction of metal filament lamps, in spite of adding on new business at a greater rate than before. He had got all the motors that were to be obtained, and, therefore, must look for side lines such as cooking and other methods of applying and using electricity. In Brighton there was a fleet of 16 or 18 motor-omnibuses driven by batteries, owned by a local omnibus company, but the routes were soon to be completed for trolley omnibuses. He had given consideration to the question of adapting the electric buses for municipal purposes, and hoped that he would be able to retain a large portion of the revenue at present derived from the 'bus company. With regard to the rate for charging, he thought 1d. was quite low enough. The Brighton 'bus company had been paying this in the past, and he had no complaints. It behoved supply engineers to try and develop this class of business, inasmuch as the vehicles could be charged at times when the generating plant might be almost idle. In this way they could afford to supply at a very low rate, and the supply of current in this way would all tend to reduce works costs and to improve the load factor of the station. He had inspected some municipal electric vehicles used in Paris, and understood that the authorities were so satisfied that they were placing an order for several hundred vehicles, and in a short time the whole of the work of the city could be carried out by self-contained electrically-propelled vehicles. In that case current was being bought from a company at a substantial higher price than obtained in England under ordinary conditions.

Baillie SMITH (Convener, Glasgow Electricity Committee) suggested that the right way to introduce electric motor traction was for the Electricity Department to use vehicles themselves, and to get the results of tests which would enable them to recommend it to other Committees of their Corporations. In Glasgow the Electricity Committee had adopted the vehicle, and the first Committee which the electric vehicles were to be recommended to was the Health Committee, for their motor-ambulances connected with infectious hospitals.

Mr. F. AXTON (Chief Electrical Engineer, Ipswich) expressed the opinion that the electric battery vehicle business from a central-station point of view was going to be just as important. He suggested the formation of a special Committee to go into the question in co-operation with the manufacturers. There were many points which ought to be settled at an early stage: for instance, the uniformity of the charging voltage, the question of the standardisation of the charging connections, and the rates. They should beware of relying too much on experience from America, as had been done in the case of tramways. It was worth while discussing as to how we should start. Should supply-station engineers start by inaugurating a garage or some place where cars could go to be charged? He had spoken to some of his automobile friends on this matter, and from what he could gather they would not move very quickly in this matter. They did not understand the electric vehicle, and were afraid of anything electrical, and considered that they had quite enough trouble as it was with the electric circuits on the petrol vehicle. It would probably be necessary to establish charging stations

in each town, and perhaps go a little further and at the first outset do any repairs which might be necessary. He admitted this was a big question, but it was one which his suggested Committee might go into. He would like to hear some witnesses' views as to how to start. In regard to the details of design, he was inclined to doubt the wisdom of chain drive for commercial vehicles. The manager of the Bradford tramway system, Mr. Spencer, who also ran trolley omnibuses, told him that the 'buses which he had and which were provided with chain drive were going to be scrapped for the reason that the chain drive had proved a failure. In the new 'buses there would be two motors, one on each side, each driving one of the wheels independently through a worm gear, and he would like to hear whether Mr. Watson did not think in the light of what he had said that the worm drive was probably the better method.

Mr. J. W. BEAUCHAMP (Chief Electrical Engineer, West Ham) could not say that they had sold any vans in West Ham, but they had had a large number of inquiries, and he believed they would get some business before long. The use of these vans should first be pushed for shifting heavy loads at low speeds. The future of the thing was really in the hands of municipalities, all of whom had much of this work. By utilising the vans in this way, they could prove the economy of them. The experience of the Commonwealth Edison Company in America seemed to prove the advantage of the use of such vans by an electric supply department. By utilising them and superseding the ordinary methods, for instance, of sending out jointers, &c., in big towns, it would be possible to save the cost of such a van several times over. With regard to a tariff, he believed that ½d. a unit was a very good one, and would bring in a revenue of about £25 a year, and as the vans could be charged off peak with very little arrangements indeed, the average load factor of charging these vans would be 40 or 50 per cent. The question of providing charging stations and things of that kind was one in connection with which they could begin almost immediately to compile a list of places where such facilities could be provided.

Mr. R. A. CHATTOCK (Chief Electrical Engineer, Birmingham) anticipated a very big business from this class of supply. The only way in which electric supply departments could assist was by regulating their rates to accommodate this class of supply. A penny per unit had been mentioned that morning as being a fair figure. This was the ordinary charge for power in most towns, and that rate could undoubtedly be charged all day long, but he assumed on the top of that rate for current the cost of the garage and the handling of the charging would have to be added, amounting, perhaps, to another ½d. per unit. He was of opinion, however, that it would pay to charge a less rate than a penny if they could restrict the hours of charging to night or to times in the day when the demand was slight. He did not favour municipalities undertaking garaging and repairing of these automobiles. This was hardly within their province, and from inquiries which he had made in Birmingham he was convinced that the ordinary garage proprietors were fully prepared to undertake this side of the business.

Mr. SYKES (Glasgow) thought that it would be quite time to regulate the price for current when the electric vehicle industry had got formally established.

Mr. L. B. HOGARTH (Chief Electrical Engineer, Morecambe) said that the matter interested him, as his Corporation was considering the question of the electrification of the Morecambe tramways, and wished to avoid adopting the overhead system. As probably several of them knew, they had in Morecambe petrol tramcars running on a route about a mile long, but if anybody suffered from liver complaint a ride on these cars occasionally would either kill or cure it. From the figures that had been obtained from the Edison Storage Battery Company, he thought that there was a great future for battery system if they could only extend their guarantee for a period of three or four years. The advantage of the electric battery vehicle was that, by allowing an overlay of about ten minutes, the vehicles could all be charged up in the daytime ready for running during the evening, thus necessitating no interference with the peak load at all.

Mr. F. W. CRAWTER (Chloride Electrical Storage Co.) said he believed he was the first driver of an electric automobile in this country, in 1888. He believed the first electric vehicle which ran in London was one improvised by Professor Ayrton in 1885. Then came Mr. Radcliffe Ward's 'bus in 1886, and then the Immisch Company in 1888, 1889, 1890, made various vehicles for export. It was no good people working alone in this matter, and both the battery people and the supply-station people must work together. Therefore he welcomed heartily the efforts of the authors to popularise the electric vehicle. He did not think the pleasure vehicle would be developed in this country to the same extent as in America, because there were large towns situated large distances apart, and the electric pleasure vehicle was used simply as a town vehicle. In London, if a person had an electric vehicle to take him to his office five or six days a week, on the other day he might want to go to Wales. For commercial vehicles it was quite a different proposition. There was an enormous field, particularly in shifting heavy weights, for the electric vehicle. The Authors gave the

average life of a lead battery as being 3,000 miles. This, however, was about one-third lower than it ought to be.

Mr. F. S. GROGAN (British Electric Transformer Co.) said that the question must be divided into two items—namely, the pleasure vehicle and the commercial vehicle. The question of the tariff would be decided on the commercial side as between the engineer in the district and the commercial firm who were running the vehicles, as such arrangements could be made as would get the least charging prices during the night. With the pleasure vehicle it was a different matter. A man might come into the town in order to get electricity at any time of the day or night, and they could not do that for a penny or anything like it. He supported the suggestion that a committee should be formed to work on co-operative lines so that they would be able to loan batteries ready charged from charging stations all over the country, and a pleasure vehicle could pay for a charged battery that would run him into another town where he could return it to the charging station there and take another.

The PRESIDENT said this question had occupied his attention some 10 or 12 years ago, and he felt that if anything was to be done at all it would have to be done like the clearing house for railways. Standardised batteries would have to be adopted, and the larger cars could have to have a larger number, and each central station would have a certain number of these batteries in their works, a small town a few, and the larger towns a larger number, so that the owners of cars would, when arriving at a town, go to a central station, where there would be facilities for taking out their battery and putting in a fresh one immediately. He concluded with some amusing remarks on the rates charged for electric launch charging on the Thames.

Mr. WATSON, in reply, welcomed the formation of a committee such as had been suggested. Without the supply-station engineers, the vehicle-makers could do nothing.

AFTER the meeting members inspected the examples of electric vehicles which had been brought to Kingston as a practical illustration of Messrs. Watson and Mitchell's Paper, and included the now famous Arrol-Johnston-Edison car, which successfully accomplished the journey from Dumfries to London mentioned in our columns recently. Some members also paid a visit to the Kingston electricity works, where interest was shown in the horizontal Diesel engine sets. A lunch at Nuthalls, an enjoyable trip up the river in steam launches, a short inspection of the grounds at Hampton Court (admission to the Palace was not allowed, although Mr. Edgcome had offered to guarantee that the ladies would not carry hammers), and a supper at Nuthalls concluded the day's proceedings.

## ANNUAL GENERAL MEETING

The annual general meeting was held in the building of the Institution of Electrical Engineers on Friday.

### A Birmingham Meeting and President in 1914.

Mr. R. A. Chattock, Senior Vice-President (Chief Electrical Engineer, Birmingham) was unanimously elected President for 1913-14, and he invited the Association to Birmingham for next year's meeting, an invitation which was accepted unanimously.

### Election of Vice-Presidents and Council.

Mr. H. Richardson, Junior Vice-President (Chief Electrical Engineer, Dundee), was elected Senior Vice-President, and Mr. A. C. Cramb (Chief Electrical Engineer, Croydon), Junior Vice-President. There were no other nominations.

### Election of Members of Council.

According to the Articles of Association, four Engineer Members of Council retired, viz., F. Ayton (Ipswich), A. C. Cramb (Croydon), F. M. Long (Norwich), and T. Roles (Bradford).

The nominations for the resultant vacancies were: W. Wyld (Hampstead), S. E. Fedden (Sheffield), H. R. Burnett (Barrow-in-Furness), A. H. Shaw (Ilford), E. E. Hoadley (Maidstone), T. Roles (Bradford), H. W. Bowden (Poplar), C. S. Davidson (Barnes), W. C. Pickvance (Wrexham), F. Ayton (Ipswich), and A. S. Barnard (Walsall).

The following were elected: S. E. Fedden (Sheffield), T. Roles (Bradford), F. Ayton (Ipswich), W. Wyld (Hampstead).

Three Chairman Members retired from the Council under the rules, viz., Alderman Crowther (Sheffield), Alderman Sinclair (Swansea), Bailie Willock (Glasgow).

The nominations for the resultant vacancies were: Alderman Littler (West Ham), Alderman Sinclair (Swansea), Bailie Willock (Glasgow), Councillor Ellaway (Birmingham), Alderman Barge (Poplar), Alderman Crowther (Sheffield).

The following were elected: Councillor Ellaway, Bailie Willock, and Alderman Sinclair.

The honorary officials were re-elected as follows:—Hon. Solicitor, Alderman Pearson (Bristol); Hon. Treasurer, J. E.

R. A. CHATTOCK.  
(President of the I.M.E.A.)

Edgcome (Kingston); Hon. Secretary, H. Faraday Proctor (Bristol).

## COUNCIL'S REPORT

THE following are the main points in the Council's Report, which was taken as read:—

**Sub-Committees.**—The Standing Committees during the year have been as follows:—

**PARLIAMENTARY.**—C. E. C. Shawfield, R. A. Chattock, H. Richardson, Alderman Pearson, H. Faraday Proctor, J. E. Edgcome, A. C. Cramb, Alderman J. P. Smith, Councillor Crowther.

**FINANCE AND GENERAL PURPOSES.**—C. E. C. Shawfield (Chairman), R. A. Chattock, H. Richardson, Alderman Pearson, H. Faraday Proctor, J. E. Edgcome, A. C. Cramb, W. W. Lackie, C. Furness, F. M. Long, J. Christie, S. J. Watson, Alderman Sinclair, T. Roles.

**EDITING.**—C. E. C. Shawfield, G. Wilkinson, H. Richardson, F. M. Long (Chairman), S. J. Watson, S. L. Pearce.

**Information Bureau.**—There is not sufficient evidence that such a bureau would be adequately supported or be of any very material benefit to the members, and the Council consider that the present system of filing information with the Secretary would meet all reasonable requirements if members made a point of forwarding information likely to be of general use. The Council is frequently called upon by members for advice on points arising in their business, and during the past year they have been able to express their views on various matters such as liability for accidental damage, the action of gas companies in seeking powers to supply electricity, and on various other subjects.

**Supplementary Paper.**—A Paper by Mr. A. M. Reid, Chief Accountant, Dundee Corporation, on "Reliability of the Total Costs per Unit Sold," will be published in the *Proceedings*.

**Travelling Studentship.**—There were again no entries for this. The Council feel that the Associates lose much of educational value by neglecting this opportunity of extending their experience and knowledge.

**Testing of Materials.**—In the last annual report (ELECTRICAL ENGINEERING, Vol. VIII., p. 373) attention was drawn to the apparent lack of reasonable facilities for the testing and certification of materials used in the electrical industry, and to the steps taken by the Council to approach the National Physical Laboratory and the I.E.E. with a view to their co-operation. After further consideration the Council felt that the matter was one which could be dealt with more effectively by the I.E.E., if they would consent to do so, and it was accordingly

left to them to continue their investigations (see also *ELECTRICAL ENGINEERING*, Vol. VIII., p. 703).

**Electric Supply Publicity Committee.**—The Council were approached by the Committee with a view to getting some of the larger municipalities to support a scheme financially for an extension of the Committee's proposals on a large scale. The difficulty was and is that many local authorities are at present debarred from spending money on publicity, and until the I.M.E.A. Bill is passed, the electrical industry will continue to be hampered and to be unable to compete with other industries in regard to developing its resources.

**Rating of Metal Filament Lamps.**—The Council has, through their representatives on the Lamp Standards Committee, been kept in close touch with developments, and some time ago expressed the view that metal filament lamps should be marked with both candle-power and wattage. Eventually, however, it became clear that there was a growing disposition on the part of makers and central-station engineers in favour of rating in watts in place of candle-power, and after further inquiry the Council had reason to modify their previous view and to express themselves in favour of rating in watts.

**Supply of Electrical Energy Conditions.**—These conditions needed revision and amendment. They have been withdrawn from publication, and a Sub-Committee has been appointed to report upon the matter.

**Electric Lighting Bill.**—The Bill promoted by the Association was down for second reading in the House of Commons on June 10th, 1912, but was not reached. Although no progress has been made in Parliament this session, a very great deal has been accomplished in reconciling the interests of all who will be affected by the measure, and there is every reason to hope that in the next session of Parliament it will be made evident that the one object of the Bill is to increase the output and diminish the cost of electricity, and to promote the general welfare of the electrical industry for the benefit of the community generally, in which efforts every section of the electrical industry is concerned.

**Sheffield Corporation Bill.**—The Council, at the request of the Sheffield Corporation, circulated the members of the Association last December asking them to endeavour to get their respective Parliamentary representatives to support Clause 83 of that Bill, referring to the supply of electric fittings by the Corporation.

**Conditions of Contract.**—The Council have under consideration the standardisation of conditions of contract with a view to agreeing upon a document which will be acceptable as a basis for such conditions between the purchaser and the contractor. A joint meeting of representatives of the British Electrical and Allied Manufacturers Association and the Association has been held, and the negotiations are still proceeding. In the meantime the Council has notified the members that the proposed conditions have not yet been agreed so far as the Association is concerned.

**Meter Loans.**—The Council were asked by the B.E.A.M.A. to approach the Local Government Board with a view of getting the term extended to ten or fifteen years. The Council, however, felt that it would not be wise to ask for more than five years, as in their opinion the purchasing of cheap meters is not due to the short loan repayment periods granted by the Local Government Board, but to the too common practice of municipalities accepting the lowest tender irrespective of other considerations.

**Publication of Tenders.**—The question of the publication of prices of municipal tenders in the technical journals has been considered at the suggestion of the B.E.A.M.A., and they invited the members not to publish lists of tenders. The members with one or two exceptions agreed with the action of the Council.

**Exhibitions.**—The question of the organising of exhibitions and demonstrations has also received preliminary consideration by the Associations jointly.

**Census of Production.**—At the invitation of the Board of Trade, the Council considered the proposed census of production form and made certain suggestions for modification. These recommendations were subsequently substantially adopted by the Board of Trade.

**Joint Conventions.**—At the wish of the Institution of Electrical Engineers the feeling of the I.M.E.A. Council regarding closer relationship between the two bodies and the holding of Annual Joint Conferences in place of the I.M.E.A. Annual Conventions was ascertained. The majority were averse from the proposal in principle, though several saw no objection to an occasional joint conference. The opinion was expressed that the interests of the two bodies were entirely different and distinctly opposed in some instances, and the Council therefore did not consider it to be feasible to hold joint Conventions.

**Constitution of the Council.**—Certain changes have been decided upon, and these were passed at a special general meeting which followed the ordinary business meeting. Briefly, the alterations made consist in the adoption of the method of electing Council recently adopted by the I.E.E., in the increase of the engineer members of Council from 8 to 9, the Councillor members remaining at 6 as before, and the adoption of a new

rule by which an "honorary" member of Council shall also be eligible, who must be a member of the Electricity Committee of the President for the year.

**Information Bureau.**—A member asked whether it was the intention of the Council to drop the proposal for an information bureau altogether. Only the other day he had an inquiry form with 16 questions to answer, which, if he had conscientiously endeavoured to do, would have taken him all the morning. The Honorary Secretary said that the only difficulty in connection with this matter was that of expense. It would mean having a paid technical officer for the purpose; he thought they would have to wait until they got the I.M.E.A. Bill through, when perhaps municipalities might be in a position to subscribe on some different basis than a mere annual subscription of a guinea.

**Election of Honorary Member.**—A vote of thanks was passed to Mr. C. E. C. Shawfield for the services he had rendered the Association; he was elected Honorary Member.

A discussion upon other matters followed, which the Press were requested not to report, and the Council's Report and Balance Sheet were then adopted.

### Other Business.

Mr. C. Turnbull (Tynemouth) hoped that there should be another discussion *in camera* next year, and suggested heating and cooking, which had been curtailed this year on account of the discussion on the I.M.E.A. Bill.

Mr. S. E. Fedden asked if it was proposed to have another exhibition of electrical cooking apparatus at the next Convention, as there should be a number of improvements during the year.

Mr. H. R. Burnett asked the Council to consider seriously the question of the salaries paid to central-station engineers and their assistants, which were in some cases an absolute disgrace to the Association. The Association was in a unique position with regard to this matter, inasmuch as they had Chairmen Members.

The President said that all these three matters would be considered by the Council as favourably as possible. There had, he added, been some misunderstanding in certain quarters as to why such a subject as heating and cooking should be discussed *in camera*. It apparently was thought that the Association had met to discuss the question as to whether or not it was possible to cook electrically, and in these circumstances perhaps it was advisable to explain that it was not for this reason, but because there were many points the members wished to discuss without hurting the feelings of manufacturers.

### Committee re Electric Vehicles.

Mr. F. Ayton moved "That a committee be appointed by the Council to consider and adopt such measures as may be found desirable to further the use of the electric battery vehicle; that such committee be empowered to co-opt representatives of other institutions, company-owned electric supply undertakings, manufacturers, and others directly interested in this matter."

Mr. A. H. Seabrook seconded the resolution, which was also supported by Mr. W. A. Vignoles and Mr. G. Wilkinson, and was carried unanimously.

At this point the meeting was declared private, and the Press withdrew.

**Prime Movers for Electric Power.**—Mr. R. W. Weekes was misunderstood by our Reporter on one point in the course of his remarks reported on page 355 of our last issue. In the example mentioned in line 24, it is stated that 6 per cent. of the total heat in the steam was lost, but what Mr. Weekes intended to imply was that 6 per cent. only was abstracted by the engine from the steam on its way from the boiler to the heating system.

**Electrical Fatality.**—An inquest was concluded last week into the death of F. Hardell, who was fatally burnt on May 1st at the Blaydon substation of the Newcastle-on-Tyne Electric Supply Co. It appears that the deceased was making some tests at the back of a switchboard on some transformers which he had connected up against instructions, and accidentally caused a short circuit by touching a piece of metal on to a terminal.

**American Hydro-electric Schemes.**—The Bill favoured by the New York Conservation Commission, which provided for the State ownership and management of water-power schemes for the generation and distribution of electrical energy in New York State on similar lines to the scheme in operation at Ontario, was recently vetoed by the Governor of New York. According to the *Electrical World* (New York), a commission is to be appointed to consider this project, and also the Long Sault, Niagara, and Genesee water-powers, and to report and submit appropriate Bills for the consideration of the next Legislature.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,344.

In what way can the forces on transformer coils due to short circuit be determined in three-phase core type and single-phase shell type transformers with sandwich windings?—J. W.

(Replies must be received not later than first post July 3rd.)

### ANSWERS TO No. 1,342.

What is the greatest error commonly met with when using single-phase dynamometer-type indicating wattmeters on power-factors down to 0.3 with frequencies varying from 15 to 100 cycles per second? The instruments consist of a single moving coil for the pressure circuit, and two fixed coils for the current circuit, no iron being used.—"Vivo."

The first award (10s.) is given to "OHM" for the reply given in slightly abridged form below:—

The errors in dynamometer-type indicating wattmeters, resulting from power factor and frequency variations, are due to two fundamental causes:—(1) The very small phase displacement between the current through the potential circuit, and the voltage to which this circuit is connected. (2) The very small phase displacement between the flux produced by the series windings and the series current. This may result from masses of metal used in the construction of the instrument, and which intercept the series flux. If iron is employed for the purpose of augmenting and concentrating the magnetic field, there will be a slight phase displacement due to hysteresis.

If no iron is used in the instruments, and it has been designed with a view to eliminating eddy currents, we need only concern ourselves with the probable error in the instrument reading due to cause (1). The armature circuit must necessarily be slightly inductive, so that the armature current will lag by a very small angle behind the voltage. The error that results therefrom is inherent, and cannot be entirely eliminated. It can, however, be reduced to a minimum by very careful design, and in most commercial instruments it does not reach a serious figure except under abnormal conditions.

If the self-induction of the armature coil =  $L$ , the total resistance of the armature circuit =  $R$  and the frequency =  $f$ . Then  $\tan \phi = \frac{2\pi fL}{R}$ , where  $\phi$  = phase displacement between armature current and voltage. For all practical purposes it can be assumed that the armature current is directly proportional to  $E$  (the voltage), as the error resulting from the variation in the armature current consequent upon a frequency change is negligible.

If  $C$  = series current, and  $\theta$  = phase displacement between  $C$  and  $V$ , the wattmeter will read  $\frac{\cos(\theta - \phi)}{\cos \theta}$  times what it should do. That is, the error in the reading expressed as a percentage will be

$$\frac{\cos(\theta - \phi) - \cos \theta}{\cos \theta} \times 100.$$

On an inductive circuit the wattmeter will read more than it should do, whilst on a circuit giving a "leading" current the reading will be on the low side.

This equation also shows that as  $\phi$  increases the error will increase, and *vice versa*. Equation (1) shows that for a given frequency  $\phi$  will decrease as  $R$  is increased. This means that the error with a low-voltage instrument will be much greater than in the case of a high-voltage instrument, as it is usual practice to employ the same armature for all voltages, and simply vary the non-inductive resistance in series with it to give the same armature current. Furthermore,  $\phi$  will increase as the frequency is raised, so that, other things remaining the same, the error will be greatest in 100 cycles.

Taking the worst possible case of a low-voltage (say 100 volts) instrument working on a frequency of 100 at 0.3 power factor, and putting the self-induction at an average figure of 0.0085 henries, and assuming  $R=3,000$  ohms, the error works out to only 0.5 per cent. This error will vanish on a frequency of 15, whilst on 100 cycles it will be negligible if the power factor closely approaches unity. Furthermore, in the case of a high-voltage instrument (say one designed for 500 volts), the error would be of no practical importance, even on 100 cycles, when the power factor is 0.3. "Vivo" will find that instrument manufacturers will be willing to guarantee the accuracy of "first-grade" instruments on all frequencies and power factors likely to be met with in practice as follows:—1 per cent. between middle point and full-scale reading; 2 per cent. at 25 per cent. of full-scale reading; 5 per cent. at 10 per cent. of full-scale reading. This guarantee is in accordance with that specified by the Engineering Standards Committee for "First Grade" Instruments.

The second award (5s.) is made to "AGATE" for a reply given in abstract below:—

The principal errors met with in single-phase dynamometer type indicating wattmeters are due to: Self-inductance of pressure circuit, capacity of pressure circuit, mutual inductance between current and pressure circuits, eddy currents, and imperfect elasticity of spring or suspension; but, with the exception of the first, all these errors are negligibly small in a good instrument. Indeed, in such an instrument, at all normal frequencies, power factors, and voltages, the error due to the self-inductance of the pressure circuit is also negligibly small, for in the design of the instrument, the pressure circuit is arranged in such a way that the reactance is small in comparison with the ohmic resistance, consequently the current in the thin wire circuit is practically in phase with the pressure. At ordinary frequencies, under certain conditions, particularly low power factor or low circuit voltage, the error due to the self-inductance of the pressure circuit may assume serious proportions.

"Agate" works out his correction factors as  $1 - \tan \theta \tan \phi$ , where  $\phi$  = the angle of lag of the main circuit and  $\tan \theta$  = the ratio reactance to the resistance of the pressure circuit.

In the case of a wattmeter where  $L=0.01$  henry,  $r=1,000$  ohms, and the frequency = 15 cycles, the correcting factor for  $\cos \phi = 0.3$  is worked out as 0.99700, which is an equivalent percentage error of 0.3 per cent. With a frequency of 100 cycles per second, and the same power factor, the correcting factor is 0.98000, or a percentage error of 2 per cent. This instrument is intended for use on 30-volt circuits. On a circuit of a power factor of 0.9 the correcting factors are 0.99954 and 0.99696 at 15 cycles and 100 cycles respectively; the corresponding percentage errors being 0.04 per cent. and 0.3 per cent. respectively.

The same instrument is used on 300-volt circuits by increasing the resistance of the pressure circuit to 10,000 ohms. Taking the case of the load of  $\cos \phi = 0.3$ , and frequency 15 cycles, the correcting factor is 0.9997, and at 100 cycles 0.9980, the corresponding percentage errors being 0.03 per cent. and 0.2 per cent. The foregoing examples suffice to show that on low voltage circuits of low power factor (such as would be used for the determination of iron losses by the Epstein method) that a knowledge of the instrument constants is of prime importance. Their determination is somewhat difficult, but, as a rule, manufacturers supply the information with their instrument.

### ANSWERS TO CORRESPONDENTS

O. HULIN.—We should advise you to write to the Secretary of the Institution of Electrical Engineers, Victoria Embankment, W.C., for particulars of the examinations.

**Memorial to Lord Kelvin.**—A bronze statue of the late Lord Kelvin, 10 ft. high, which is the work of Mr. A. Bruce-Joy, was unveiled by Sir Joseph Larmor, F.R.S., on Thursday last at Belfast.

### A RED-HOT HOT-PLATE

WE recently had the pleasure of inspecting some of the latest products of the works of Belling & Co. (Enfield). Of greatest interest at the present time, in view of the recommendations of the "Point Fives" in this connection (ELECTRICAL ENGINEERING, June 5th, p. 321), is a 1.5 kw. red-hot hot-plate. From the illustration, Fig. 1, it may be seen that the hot-plate consists of a cast-iron top and a spun-steel well, between which are housed the heating element and heat insulation, preventing heat escaping downwards. The actual heating element consists of a porcelain former, unglazed on the top, but glazed underneath. A number of peg-like projections are distributed uniformly over the upper surface as shown, and the resistor in the form of a small spiral of nichrome wire is suitably held in place by the pegs. The resistor is divided into two sections, so wound that in no case is the pressure between adjacent turns more than

FIG. 1.—THE BELLING HOT-PLATE.

a few volts. The heat is equally distributed, and, moreover, a too intense central heat is avoided, thus overcoming expansion troubles. Three heats may be obtained. When the resistor is in position it is covered by a special fireproof cement pressed well in. Whilst it is drying current is passed intermittently through the wire, so that a small space round all parts of it is formed to provide for expansion when in actual use. On the cement is a further layer of a fine heat-conducting, non-caking powder which, owing to the construction of the hot-plate, sustains a continual uniform pressure. The leads are brought to the terminal well in flexible metallic tube, and by means of the removable bottom cover the hot-plate may be entirely disconnected in five minutes. The whole plate rests on three locked adjusting screws, so as to get correct top level. It should be noticed that, owing to the construction, no water can drip on to the element or into the terminal box.

These hot-plates may be obtained singly mounted on a suitable stand, and they are used in the Belling domestic cooker, which is provided with side heat in the oven, the

FIG. 2.—FRONT AND BACK VIEWS OF THE BELLING DOMESTIC COOKER.

elements of which are easily get-at-able, and yet out of harm's way. It may be mentioned that the oven gives excellent results, and the whole design appears to make for simplicity, ease of operation, cleanliness, and durability, as may be seen by the illustrations in Fig 2, which shows both front and back views. By using improved fire-bars and winding the resistor first into a helix, it is now possible to supply single bars for pressures up to 500 volts, and the new terminal clip (ELECTRICAL ENGINEERING, June 12th, p. 331) gives a

large cooling surface to the wire, which is effectively prevented from coming in contact with the fixing screw. Thus the danger of breaking the wire when connecting up is eliminated.

Among the other specialities may be mentioned a radiant-heat grill and many handsome "electric fires," which are to be on the market this season. Messrs. Belling & Co. are about to move into larger works at Edmonton.

### BOARD OF TRADE REGULATIONS FOR THE ACCURACY OF METERS

IN pursuance of the provisions of Section 11 of the Electric Lighting Act, 1909, and of the provisions substituted by that section for Section 50 of the schedule to the Electric Lighting (Clauses) Act, 1899, and for the corresponding provisions contained in or incorporated with any special act or provisional order relating to the supply of electricity, the Board of Trade have made regulations allowing the following limits of error for electricity meters, the construction and pattern of which have already been or may hereafter be approved by them, and belong to the classes of meters capable of ascertaining the value of the supply on continuous current or on single phase alternating current circuits.

Meters in which the maximum current for full load (a) does not exceed three amperes—the error at any point from one-tenth load to full load must not exceed  $3\frac{1}{2}$  per cent. plus or minus; (b) exceeds three amperes, but does not exceed 50 amperes—the error at any point from one-tenth load to full load must not exceed  $2\frac{1}{2}$  per cent. plus or minus; (c) exceeds 50 amperes—the error at any point from one-twentieth load to one-tenth load must not exceed 2 per cent. plus; and at any point from one-tenth load to full load must not exceed  $2\frac{1}{2}$  per cent. plus or minus.

### THE GLASGOW ELECTRICAL EXHIBITION

ARRANGEMENTS are proceeding apace for the Electrical and Engineering Exhibition, which is to be held in Glasgow from October 28rd to November 15th, at the Zoo Buildings, New City Road. The success of the exhibition is already assured by the large proportion of space let to leading firms, and the fact that the British Electrical and Allied Manufacturers Association has agreed to give their support. Among the exhibitors who have already taken space are the following: the Glasgow Corporation, British Insulated & Helsby Cables, the Electrical Co., Siemens Bros., Anderson & Munro, Verity's, Edison & Swan, M. K. Cooper & Co., Electric Control, Ltd., British Electric Plant Co., British Thomson-Houston Co., Fraser & Borthwick, W. T. Henley's, Bonham Scott & Co., Brown, Boveri & Co., Callender's Cable & Construction Co., Electric Appliances, Ltd., Scottish Vacuum Cleaner Co., Magic Appliances, General Electric Co., British Westinghouse Co., R. Waygood & Co., Kelvin & James White, British Heaters Co., Carrier Co., Simplex Conduits, J. Keith & Blackman, Yates Bros., J. Dugdill, Edward & Sons. A special feature will be cinematograph demonstrations of the uses of electricity.

### CATALOGUES, PAMPHLETS, &c., RECEIVED

**BATTERY FANS.**—A neat little four-bladed ceiling battery fan for use in motor-cars, boats, yacht-cabins, motor-buses, &c., is described in a new leaflet from the General Electric Co. (67 Queen Victoria Street, E.C.).

**GAS ENGINES.**—A pamphlet from Crossley Brothers, Ltd. (Openshaw, Manchester), describes their exhibit at the forthcoming Royal Agricultural Show at Bristol, where they will be showing a new design of gas and suction gas plant.

*Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."*

**FIBRE, EBONITE, BELTING, &c.**—A list from Arthur Cort & Co. (303½ Camberwell Road) deals with vulcanised fibre, ebonite, vulcanite, Chatterton's compound, gutta-percha, and other materials, as well as balata, gutta-percha, and cotton belting.

## TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

The appeals and cross-appeals resulting from the arbitration proceedings before the Railway and Canal Commissioners, who had to determine the price the Government should pay the National Telephone Co. for its undertaking, have been settled out of court. It will be remembered that, after the award by the Railway and Canal Commissioners, the Post Office appealed to the Court of Appeal on the point that nothing at all ought to have been allowed for the "cost of raising capital, &c." The Telephone Co. then entered cross-appeals practically alleging that much of the award was bad. When the appeals came before the Appeal Court, which Court thought it had the right to hear the appeals, the Telephone Co. argued that under the constitution of the Court of the Railway and Canal Commission there was no jurisdiction to appeal, but if there was, the Telephone Co. would cross-appeal on several points. This point was taken to the House of Lords, who took the view that there was an appeal from the Court of the Railway and Canal Commission to the Court of Appeal, and a preliminary objection taken by the Attorney-General that no appeal lay from the Court of Appeal to the House of Lords was overruled. As a result of this, the appeal was to have been continued in the Court of Appeal before the Master of the Rolls and Lords Justices Kennedy and Swinfen Eady on Monday, but before the case was called the leading counsel held a private consultation with the judges. As a result of this it was announced that an agreement had been come to, which would be announced on Tuesday next, as certain formalities had to be complied with.

Owing to the breakdown of a cable in the south-eastern district, telegraphic communication between London and Woolwich was interrupted last Thursday night, and messages were sent round through Eltham. A gang of men from headquarters were at work all night effecting the necessary repairs.

At the meeting of the Marconi International Marine Communication Co. the Chairman announced that the profit had increased by nearly £10,000 over that of the previous year. A 10 per cent. dividend was declared.

In view of the fact that on and after July 1st time signals will be transmitted daily at 10 a.m. and 12 midnight from the great Eiffel Tower Wireless Station (in direct connection with Paris Observatory), and from the German Norddeich station at 12 noon and 10 p.m., the Synchronome Co. (32 and 34 Clerkenwell Road) have brought out a complete wireless receiving set designed for watch and clock makers. The necessary instruments are combined on a neat board occupying little space, and the whole outfit is appropriately called a "Horophone." No technical knowledge in the use of the apparatus is required, and, thanks to its simplicity, it can be sold at a low price. Mr. Hope-Jones, of the Synchronome Co., points out that the watch and clock trade in France were making extensive use of the wireless time signals, and sees no reason why the same should not be done here. Some particulars of the signals from the Eiffel Tower were given in *ELECTRICAL ENGINEERING*, May 20th, p. 306.

We have received from the Italian Ministry of Posts and Telegraphs a copy of a well-printed and illustrated volume partly in French and partly in Italian, forming a complete record of the International Congress on practical telegraphy, held at Turin during the Exhibition in 1911. Numerous portraits of the participants and views of the actual meetings are given, with a full account of the proceedings, which included prize competitions in sending and receiving. Other sections are devoted to the Volta commemorations, including fêtes held at Milan, a postal congress in Rome, and an interesting article commemorates the jubilee of the Italian postal and telegraphic services.

On the 17th inst. the Tangier-Arzila line gave out again, and telegrams for the French zone cannot now be accepted, urgent messages being sent by wireless, and these can only be accepted conditionally.—The Campagnie Française des

Cables Télégraphiques successfully repaired the Paramaribo-Cayenne cable on the 19th inst., and the recently repaired section between Martinique and Paramaribo once more requires attention, having failed on the same day.—Telegrams for French and Dutch Guiana, as well as for other places via Hayti, are stopped, and messages must be sent via Salinas.

## ELECTRIC TRACTION NOTES

Direct-current battery storage has been adopted for the Wiesenthal single-phase line of the Baden State railways. According to *Elektrische Kraftbetriebe und Bahnen*, the railway pays a fixed sum to a local supply company for energy up to a maximum demand of 1,040 kw., with an increased rate for the units taken over this limit; and the battery storage has been adopted to reduce the maximum demand. The current is supplied three-phase 50 cycles to the sub-station at Basle, which contains two three-phase single-phase motor-generators, each with a direct-current machine direct-coupled. The single-phase generators supply the railway feeders at 15,000 volts 15 cycles, and the direct-current machines act as generators, charging the battery at periods of low railway load, and at times of heavy demand, as when one or more trains are starting, act as motors, taking energy from the battery and helping to drive the single-phase generators. The battery has a capacity of 2,200 ampere-hours at 750 volts, and can deliver 4,800 amperes for a short time. The sets are controlled by direct-coupled Danielson double-commutator machines, which also provide automatic compounding of the single-phase generators. It is stated in the Swiss papers that some of the German locomotives made for this railway have not come up to expectations in their tests, and that the aid of a steam locomotive had to be requisitioned to enable them to start with full load. Alterations are being put in hand, but in the meantime an order for two new locomotives has been given to the Swiss firm of Brown, Boveri & Co.

Lectures on electric traction are being given at Euston and provincial centres of the London & North Western Railway to members of the staff by Mr. F. A. Cortez Leigh, Chief Electrical Engineer to the railway, in view of the approaching conversion to electric traction of the Company's suburban lines.

A considerable length of guard-wire which had come into contact with the trolley-wire in Harrow Road, near Paddington Green, fused and fell into the roadway one evening last week. No one was injured.

The Railless Traction Bill of the Mexborough and Swinton Tramways has passed through the Select Committee. The much-discussed clause as to road maintenance has been settled so that the Company shall bear one-third of the cost of certain road widenings, and contribute a fixed sum of 3d. per car mile to road maintenance.

The London County Council are unwilling to accept the clause inserted by the Select Committee in the L.C.C. Tramways and Improvements Bill, giving the London United Tramways Co. running-through powers over certain of their lines, and at Tuesday's meeting passed a resolution that steps be taken to secure its deletion.

The Board of Trade report of Col. Druitt on an accident on the Lancashire & Yorkshire Railway at Sandhills, Liverpool, on May 1st, when a steam train ran into the rear of an electric train. It appears that the vacuum brake of the electric train was defective, and the driver was unable to pull up at a signal which was against him, and entered a section immediately in front of an express, which dashed into the rear of his train. The lack of power of the brake was due partly to a hot bearing on a vacuum pump which entailed changing over to another pump at the rear of the train, which is less effective, and partly to the sticking of the plunger of an electrically-actuated valve, so that the connection between the train pipe and pump was not fully open.

## "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

### Specifications Published June 19th, 1913

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

5,026/12, 5,027/12, and 5,028/12. **Ductile Tungsten Filaments.** J. HUBERS (*Julius Pintsch A.-G.*). The first specification describes a process in which a compound of tungsten is mixed with between 1 per cent. and 5 per cent. of an oxide or an equivalent proportion of a compound of thorium or other rare earth metal, an alkaline earth metal or magnesium or zirconium, or a mixture. The mass is squirted and reduced in hydrogen, so as to avoid the formation of crystalline particles. The metals are finally alloyed together. Alternatively, colloidal tungsten may be used. In the second specification processes are covered for compressing the preliminary ductile filament, obtained as above described, by passing it through drawstones or rollers and subjecting it to drawing or rolling. According to the third specification, a thick wire or rod is formed from the paste, as in specification 5,026/12, and is drawn or rolled.

12,752/12. **Ductile Tungsten Filaments.** M. M. HUBERS, executrix of the late J. HUBERS (*Julius Pintsch A.-G.*). The carbonisation and decarbonisation of the filaments, produced as above in a reducing atmosphere, is effected with filaments of long aggregate length, and is carried out in one step. The filaments are cut to length after ductile filaments are obtained.

12,244/12 and 12,469/12. **Drawn Tungsten Filaments.** C. GLADITZ. In the first specification a construction of press moulds, which permits of pressing the bar in such a way as to avoid the possibility of cracking, is described. The tungsten powder used is of a fluffy character, and the press mould simultaneously and instantaneously releases the compressed bar in all three directions, so that it can expand unrestrictedly. Two figures. The second specification deals with a method of preparing the end of the wire so that it can easily be inserted into the draw-plate, for drawing into filaments, without twisting taking place. A long tapering of the wire at the end is effected by treatment in an electrolytic bath containing a strongly oxidising electrolyte. The end to be treated is stretched and hangs vertically in the electrolyte, and is connected up as the cathode, and is gradually withdrawn upwards. Four figures.

16,174/12. **Automatic Supply System.** H. LEITNER. An internal-combustion engine is arranged to drive a dynamo in conjunction with which is a storage battery whose principal function is to supply the dynamo as a motor when it is required to start up the engine. A regulator of the type covered by patents Nos. 21,145/04, 25,784/04, and 6,690/06, is used. At the end at which the travelling arm has put all the resistance in the main circuit, a trigger is provided. This, when closed, completes a circuit from the battery through the solenoid of an automatic motor starter. The ignition circuit is interconnected with the motor starter, so that the release of the solenoid will both disconnect the dynamo and stop the engine.

24,345/12. **Aerials for Wireless.** E. GIRARDEAU. The aerial described is for use with high-frequency generators. The conducting wire consists of two parts: first, the wave-radiating part, which is vertical, and secondly, a horizontal part, which merely serves for increasing the wave-length. This part is constructed as a flat, horizontal spiral. The former lies between the latter and the earth. Three figures.

231/13. **Enclosed Flame Arc Lamps.** CROMPTON & Co. and C. CROMPTON. Up-cast and down-cast circulating tubes are provided. The former are heat-insulated and provided with heating coils connected in series with the arc. Two figures.

### Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, E.C., at the price of 8d. each, post free. Summaries of some of the more important of these patents will appear in our next issue.

**Arc Lamps:** BOARDMAN, 29,160/12.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** FRENKEL [Insulated coils] 12,530/12; THOMPSON (*Ateliers de Constructions Electriques de Charleroi*) [Starting a synchronous and asynchronous machine connected in cascade] 5,481/13.

**Dynamos, Motors, and Transformers:** MCLEAN [Field magnet] 17,391/12; SIEMENS DYNAMO WORKS and HOWARD [Cooling] 18,087/12.

**Heating:** COLLINS and COLLINS [Cable connectors for irons] 20,776/12; MAYER [Heaters] 29,569/12.

**Ignition:** BOSCH [Short-circuiting gear] 27,403/12.

**Incandescent Lamps:** TOPHAM [Apparatus for feeding powdered, granular, or like material] 15,547/12.

**Instruments and Meters:** B.T.-H. Co. and YOUNG, 14,378/12.

**Switchgear, Fuses, and Fittings:** EDWARDS [Conduit continuity devices] 16,318/12; MARKS (*Clinton Wire Cloth Co.*) [Circuit-breakers for welding machines] 18,109/12.

**Telephony and Telegraphy:** MALCOLM [Concrete antenna towers] 10,542/12; GELL [Automatic switching for telegraphy] 12,847/12; AITKEN [Telephone exchanges] 12,973/12; [Telephone switching] 12,974/12; [Switchboards] 12,975/12; HEURTLEY [Telegraphy] 13,155/12.

**Traction:** ELEKTROMOTOREN-WERKE HERMANN GRADENWITZ [Transporters] 12,833/12.

**Miscellaneous:** DUSSAUD [Projection apparatus] 5,424/12; CHAPMAN (*Chapman*) [Signalling] 13,208/12; B.T.-H. Co. (*G.E.Co., U.S.A.*) [Cranes] 18,746/12.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Heating:** WEINTRAUB [Refractory materials] 20,348/12.

**Meters:** CIE. INTERNATIONALE D'ELECTRICITE, 11,825/13.

**Telephony:** SIEMENS & HALSKE, 12,060/13; [Circuit arrangements] 12,061/13; [Inductance coils] 12,565/13.

**Miscellaneous:** FEDERICO [Transmitting synchronous movements by rotating magnetic fields] 12,638/12.

### Opposition entered to Grant of Patents

9,673/12. **Direction "Tell-tales."** J. C. CLARKE and CHAD-BURNS (SHIP) TELEG. CO. This specification deals with an electrical tell-tale adapted for use with the propeller shafts of steamships. It operates in conjunction with the propeller shafts and the order telegraph through a differential gear, and a pointer is moved over a scale by electromagnets. Eight figures.

2,471/13. **A.C. Phase Transformation.** F. SPINELLI. To effect the static transformation of three-phase current into single-phase current with three times the frequency by connecting the secondaries of three single-phase transformers with highly saturated cores in series and feeding with the three-phase current. Alternatively a four-core transformer may be used.

### Expiring and Expired Patents

The following Patents expire during the current week, after a life of fourteen years:—

13,509 of June 29th, 1899. **Controlling Electric Cranes.** J. G. W. ALDRIDGE. The motor is connected to the crane barrel through a clutch which is operated in conjunction with the motor controller by the control lever. A separate brake acting on the barrel controls descending loads, as on the return motion of the control lever the barrel is entirely disconnected.

13,561 of June 30th, 1899. **Storage Battery Traction.** M. J. BARREAU. To maintain constant the effective work of the motor at different speeds, an induction coil divided into sections is arranged to be connected in various ways (the sections in series, parallel, or series parallel) between the battery, which is divided into as many parts as the induction coils, and the motor. By this means the field current may be kept constant, and the speed will vary as the applied pressure. The motor is shunt wound.

13,646 of July 1st, 1899. **Traction and Crane Motor.** T. D. HOLLICK. To start, stop, or reverse effectively and economically the armature is mounted on a shaft revolving on fixed bearings, while the field magnets can revolve freely concentrically with the shaft, on which are toothed wheels gearing with toothed wheels on the field magnet through wheels connected with the pulley shaft, which is concentric with the armature shaft. The motions of the pulley shaft are controlled by retarding either the armature or field magnet.

The following are the more important Patents that have become void through non-payment of renewal fees.

**Arc Lamps:** JOHNSON & PHILLIPS [Globe] 5,029/08.

**Distributing Systems, &c.:** M. EYQUEM [Constant pressure variable speed dynamo] 4,503/05.

**Dynamos, Motors, and Transformers:** C. H. PRÖTT [Adjustable speed polyphase motors] 4,950/08.

**Electrometallurgy:** SOC. DES PROCÉDÉS GIN POUR LA MÉTALLURGIE ELECTRIQUE [Open channel induction furnace] 1,080/07.

**Incandescent Lamps:** H. KUZEL [Colloidal filament manufacture] 5,129/06; J. W. GREENWOOD [Cycle lamps] 5,078/08.

**Switchgear, Fuses, and Fittings:** B.T.-H. Co. (*E. W. Rice, U.S.A.*) [Motor-operated remote-controlled H. P. switchgear] 4,248/00; R. P. JACKSON [Double break switch with rolling contact] 4,000/07; A. H. CURTIS, A. H. MACKLEY, and ADAMS MFG. CO. [Locking and indicating push-button switch for lifts] 4,696/08; CROMPTON & Co. and C. CROMPTON [Two-arm motor-starter and controller] 4,799/08.

**Traction:** G. HARRISON (*Elec. Rly. Improvement Co., U.S.A.*) [Electrically-welded rail bonds] 5,016/08 and 5,017/08.

**Miscellaneous:** E. W. ENGELS [Fire and acid proof materials containing carborundum] 4,166/00; L. CHALAS, E. RÉQUILLART, and C. CONTAL [Electro-magnetic horn] 4,951/06.

## LOCAL NOTES

**Aldershot: Electricity Accounts.**—A working net profit of £508 is reported, with £31 deposit interest and £264 brought forward; £477 is to be transferred to reserve and the remainder carried forward.

**Batley: Electricity Accounts.**—Last year's deficit of £37 has been turned into a net surplus of 19s. 4d. The gross profit was £3,271, nearly all of which was absorbed by capital charges.

**Bedford: Diesel Engine Prices.**—The inquiry held in April on the application for a loan of £11,590 for plant extensions was reopened on Wednesday of last week, when evidence was taken regarding the reasons for certain differences in the prices in the tenders for Diesel engines, and an arrangement that had been made between four of the five firms who had been asked to tender. A long report of the inquiry appeared in the *Bedfordshire Times and Independent* of June 20th.

**Bexhill: Electricity Accounts.**—A profit for the year of £1,086 has been made, and after deducting £421 for public lamps and meters there remained a balance of £421. During the coming year a new switchboard is to be erected at a cost of £500.

**Blackpool: Electricity Accounts.**—With a total income of £40,333 and expenditure of £20,928, there remained, after meeting capital charges, a surplus of £6,226, of which £2,426 has been transferred to reserve and £3,800 to the general district fund. The capital account now stands at £218,007; 4,725,049 units were generated during the year, with a maximum load of 3,179 kw. and a plant capacity of 6,550 kw.

**Clones (Ireland): Electricity Supply.**—Messrs. Henry Jenkinson & Co., accountants, 29 Rosemary Street, Belfast, are promoting a company whose object it will be to introduce electric light into the town of Clones. Mr. Charles Ferguson, Electrical Engineer, Fermanagh Street, Clones, has consented to act as managing director.

**Colchester: Electricity Accounts.**—The year's working has resulted in a gross profit of £7,268, which, after meeting capital charges, leaves a final surplus of £591 (against £122 for last year). There has been an increase in the works costs due to rise in price of fuel, but other items have decreased; 1,555,425 units were sold, which is an increase of 58,000 over the previous year.

**Hereford: Electricity Accounts.**—The gross profit for the year of £3,035 has been insufficient to meet the capital charges, and a deficit of £448 has resulted. The undertaking has suffered severely from decreased demand due to metal filament lamps.

**Kettlewell: Electricity Supply.**—At this little village in the Upper Wharfe Valley, Yorkshire, a water-power plant was opened recently, which is said to be the smallest public supply station at work. It was established by a local company at a cost of £625, and has a capacity of 400 lamps. Overhead distribution is used, and the mains are attached in most cases to the chimneys of the houses.

**London: Stepney.**—Notwithstanding the increased cost of coal, the net profit of £11,507 is only £1,250 less than the figure for the previous year. Of the balance of £13,760, including the amount brought forward from last year, £1,125 is to go towards capital expenditure, £2,711 is to be written off capital expenditure, £8,442 carried to reserve, and £1,482 carried forward. The works costs have been reduced to 0.594d. per unit, which is claimed to be the lowest in the County of London.

**Stoke Newington.**—A clause is to be added to the conditions of the tariff providing for a minimum charge of 13s. 4d. per quarter in the case of a consumer failing to take a supply to that amount in any quarter.

**Lynn: Electricity Accounts.**—The net profit, after allowing for capital charges, works out at £876. Of this £246 will be devoted to paying off capital expenditure for last year on meters, mains, &c., and the remainder in part payment for extensions now proceeding. The total units generated were 44,438.

**Newport: Electricity Accounts.**—The year's working has resulted in considerable increase in revenue with only slight increase in expenditure, but there is still a loss on the undertaking of £1,093 on the supply department, and £2,326 on the tramways.

**Skegness: Electricity Supply.**—Crompton & Co. have given notice of their intention to apply for a provisional order for the supply to the district.

**Tempo (Ireland): Electricity Supply.**—The inhabitants of

Tempo have decided to have a plant for electric lighting purposes installed. A company has been formed and the necessary capital subscribed. It has been decided to accept the tender of Mr. J. S. Loughlin, Bundoran, for the installation of the plant, which will be proceeded with immediately.

**West Ham: Electric Automobiles.**—We have received a copy of the excellent booklet with which the Corporation electricity department are circularising manufacturers and others in their district. The advantages of the vehicles propelled by the Edison battery are well put, and we understand that a large number of promising inquiries have already been received. The department have two Edison vans of their own in daily use.

**West Wickham: Electricity Supply.**—A Select Committee of the House of Lords has decided that unless the West Kent Electric Power Co. exercise their powers and give a supply to West Wickham within six months the supply may be given by Beckenham. The West Kent Co. have had difficulties with the Bromley Corporation through whose district the cables would have to run.

**Weymouth: Electricity Accounts.**—The gross profit of £4,538, after meeting capital charges, leaves a net balance of £881.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

## Generating Stations, Sub-Stations, Mains, &amp;c.

**Bexhill.**—A Local Government Board inquiry has been held for a proposed loan of £1,900 for substation site and mains.

**Chester.**—A Local Government Board inquiry was held last week into an application for a loan of £11,550 for a battery with building, boosters, switchgear, &c.

**Costa Rica.**—Tenders are invited for the erection and working of a hydro-electric plant to supply power to the City of Limon and neighbourhood. The plant required comprises two Pelton turbines of 414 h.p., two 400 kw. generators, and six transformers. Particulars from Commercial Intelligence Branch, Board of Trade.

**Kettering.**—A Local Government Board inquiry was held recently into an application for a loan of £1,600 for feeder cables. There was no opposition.

**Londonderry.**—A Local Government Board inquiry was held on June 14th regarding an application for a loan of £13,000 for cable extensions rendered necessary by the re-opening of the shipyard which is taking all its power from the Corporation.

**Loughborough.**—The Council has approved the expenditure of £11,000 for works extensions and £3,000 for mains. Application is to be made to the Local Government Board for sanction to a loan.

**Whitworth.**—An application to the Local Government Board is to be made by the Council for permission to borrow £10,065 for an electric lighting plant.

## Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

**Bridport.**—Isolation Hospital.

**Bury.**—Conversion to electric lighting at Gigg Mills for Bury Papermaking Co.

**Crewe.**—Co-operative Store. Architect, Mr. G. E. Bolshaw, Southport.

**Eccles.**—Tenders are invited for electric light installation at the Green Lane Council School, Patricroft.

**King's Langley.**—County Council School. U. A. Smith, County Surveyor, Hatfield.

**London.**—Reconstruction of Tivoli Theatre, Strand.

**Hampstead.**—New fire station.

**Manchester.**—New secondary school at Harpurhey.  
**Pembroke.**—New police station. H. H. Thomas, County Surveyor, Haverfordwest.  
**Rotherham.**—New Y.M.C.A. building.  
**Scarborough.**—Tenders are invited for an electric lighting installation at the Workhouse and Infirmary by July 12th. Particulars from Tennant & Barra, Consulting Engineers, Cathedral Buildings, Dean Street, Newcastle-on-Tyne.  
**Sheffield.**—Extensions to Union Hospital.

### Miscellaneous

**Australia.**—The principal of a Sydney firm, visiting London, wishes to get into touch with United Kingdom manufacturers of all classes of electrical goods and machinery. Particulars from Information Department, London Chamber of Commerce, Oxford Court, Cannon Street, E.C.

Tenders are invited by Sept. 16th for telephone exchange switchboards for Melbourne, and by Aug. 13th for telephone parts and switchboards for Adelaide. Particulars from High Commissioner, 72 Victoria Street, S.W.

**Denmark.**—A Danish firm wishes to secure the representation of United Kingdom manufacturers of armatures and other electrical machinery. Apply to the Danish Consulate-General, and 9 Byward Street, Great Tower Street, E.C.

**London:** Tenders are invited by H.M. Office of Works for a year's supply of incandescent lamps. (See an advertisement.)

**Hackney.**—The electricity department has received permission of the Council to purchase a high-pressure cable-testing set at a cost not exceeding £150.

**Norway.**—Tenders are invited by the Norwegian State Telegraph Dept. for 400,000 metres of double wire. Particulars from Commercial Intelligence Branch, Board of Trade.

### TENDERS RECEIVED AND ACCEPTED

**London: St. Pancras.**—The tenders of E. F. Moy, Ltd., for testing panels (£98), and the Electrical Power Storage Co. for cells (£86), have been accepted.

Siemens Bros. Dynamo Works, Ltd. (Incandescent Lamp and Fittings Dept., Tyssen Street, Dalston), advise us that they have obtained the following contracts:—12 months' supply of Tantalum traction-type lamps to Rochdale Corporation Tramways and Royal Mail Steam Packet Co; drawn-wire and carbon lamps to G.N. Ry. Co., and carbon lamps to the War Office.

Among recent orders for Osram lamps from the General Electric Co. are those for installations on the s.s. *City of Paris*, running between Liverpool and Calcutta, and the Brighton Palace Pier.

### MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. G. Smith & Son inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £67 15s. to £68 5s. (Last week, £69 to £69 10s.)

**Australian Prize Van.**—A prize has been awarded to the British General Electric Co. for a delivery vehicle at the Annual Show of the Royal Agricultural Society of New South Wales at Sydney.

**New Telephone Number.**—Osram Lamp Works, Ltd., inform us that on and after Saturday next their telephone numbers will be Hammersmith 1500 and 1501.

**Private Fire Brigade Championship.**—This competition was held at the Guildhall on Saturday last, the 21st June, and as a result the Robertson Lamp Section Brigade took second place and won the bronze medals; the Osram Lamp Section Brigade obtained the fourth place. There were twenty-three brigades competing.

**Change of Address.**—The British Home and Office Telephone Co. (15 and 17 City Road, E.C.) have moved to 125 High Holborn, W.C.

The General Cable Manufacturing Co. have now removed to larger and more convenient premises at 15 Garlick Hill,

London, E.C. (Tel.: City, 3408). Large stocks of V.I.R. cables are kept at the new stores, and immediate deliveries can be effected.

**Agency.**—The Arc Lamp-Lowering Gear Co., of Darlington, have appointed as their sole agents for London Messrs. Neale & Freund, Ltd., who will keep samples at their offices at 31 Budge Row, Cannon Street, London, E.C.

**Companies Struck off Register.**—The names of the following have been struck off the register of joint stock companies:—Carnarvonshire Electric Traction Syndicate; Empire Electric Light & Power Co.; and the Improved Electric Supplies, Ltd.

**Liquidations.**—The Johnson Secret Wireless Telegraph and Telephone Testing Syndicate is to be wound up voluntarily. A meeting of creditors will be held to-morrow at 40 King Street, E.C., at 2.30.

**Bankruptcies.**—A third and final dividend of 1½d. in the £1 is to be paid in the bankruptcy of J. G. Cunningham and H. P. Addison, lately trading as Laing Wharton and Cunningham, electrical engineers, 7 Great Newport Street, London.

### APPOINTMENTS AND PERSONAL NOTES

Mr. G. W. Humphreys, Chief Engineer to the L.C.C., has been nominated to replace Sir Maurice Fitzmaurice as a representative of the Council on the Engineering Standards Committee.

Mr. T. R. Stancombe, of York, has been appointed Commercial Power Engineer at Bristol.

Captain T. C. Fitz-Hugh, the Chief Commissioner in the Far East, recently appointed by the British Engineers' Association, left London for Peking, via Siberia, last Saturday, accompanied by his secretary, Mr. L. B. Stevens.

### COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

**Aron Electricity Meter.**—The report announces a net profit of £36,652 to be added to £4,455 brought forward from the previous year. After paying the preference dividends at the rate of 6 per cent. per annum, a 7 per cent. dividend is recommended on the ordinary shares, with £15,000 transferred to reserve, and £5,864 carried forward. The past year's trading in electricity meters and taximeters has again been most satisfactory, the sales having exceeded those of any previous year. The company's factories have been fully employed, and the necessary extensions to cope with the increased business are being carried out.

**Edison and Swan United Electric Light Co.**—At an extraordinary meeting of first debenture holders last Wednesday, Mr. Ellice Clarke presiding, to consider a scheme for the consolidation of the first and second debenture stocks into one stock bearing interest at 4½ per cent. per annum, on a show of hands the scheme was passed by 9 votes to 8. A poll was, however, demanded. At a meeting of second debenture holders held subsequently, the scheme was adopted with one dissentient. The result of the poll was declared on Friday to be against the scheme, as it fell short by 1,417 votes of the necessary three-fourths majority. The scheme therefore cannot proceed.

**Crompton and Co.**—According to the *Financial Times*, the directors have drawn up a scheme of reconstruction involving the exchange of the existing 85,000 ordinary £3 shares into a fresh issue (share for share) with a denomination of £1 per share, while, in addition, there will be created 136,000 non-cumulative seven per cent. participating £1 preference shares, credited as 12s. 6d. paid. These will be offered to the existing proprietors at the rate of eight new preference shares for every five shares now held. The existing £100,000 of debentures will be paid off, but the new company will be at liberty to make a further amount of £100,000 of five per cent. bonds.

**R. Waygood and Co.**—A profit is reported of £25,288, making £31,541 with the inclusion of the amount brought forward. A further dividend, making 7 per cent. for the year, is recommended, with £1,500 put to reserve and £6,691 carried forward.

**J. G. White & Co.**—The report gives the net profit on the year's trading as £88,797, out of which £10,000 is allocated to special dividend equalisation reserve, and £20,000 added to general reserve. A dividend of 12 per cent. is recommended on both classes of shares, and in addition an extra dividend of 10s. per share on the ordinary shares.

## SUMMARY

THE new buildings at the National Physical Laboratory were opened by Mr. A. J. Balfour on Thursday last. (Page 390.)

THE Annual Report of the Chief Inspector of Factories includes the report of Mr. G. S. Ram, the Electrical Inspector, who reports the same number of electrical accidents in generating stations as last year, and draws attention particularly to the question of switchboard fires. The district inspectors report an increase in lead-poisoning in accumulator factories, and a special report appears on the lighting of foundries. (Page 391.)

AN interesting Paper on Aluminium Cables was read by Mr. Welbourn before the Institution of Mining Engineers last month. Mr. Welbourn makes little of the difficulty of wiring and jointing aluminium cables, and is of opinion that the whole question is one of the relative cost of aluminium and copper. Comparisons of cost were made, to show at what market values of the two metals aluminium cables might come in for consideration with advantage. Incidentally, also, the question of lead-covered v. vulcanised bitumen cables was discussed. (Page 393.)

THE objections to the Home Office draft general regulations made under the Coal Mines Act were considered by Lord Mersey at a reference which has just terminated. It will now be compulsory to fix signal indicators in the winding engine house. (Page 395.)

THE Patents of particular interest to mining electrical engineers and electrometallurgists published during the

preceding month include one by J. H. Hoadley, for producing gas underground in mines and conveying it to the surface, and two relating to electric furnaces for the production of tin from its ores, and for the direct production of iron and steel respectively. (Page 395.)

A METHOD of differentiating between alternating and continuous-current mains and ascertaining if they are live and if they are carrying current, are discussed in our Questions and Answers columns. (Page 397.)

THE Specifications published by the Patent Office last week included one for a storage-battery portable jib crane, by the B.T.-H. Co.; one dealing with the cooling of dynamos and motors, by Siemens Bros. Dynamo Works and J. Howard, and a method of detecting the presence of icebergs or other bodies in the neighbourhood of ships at sea, by Adam Hilger, Ltd., and L. Bellingham. The method requires the use of thermopiles or bolometers. Opposition has been entered to the grant of several patents, including one by C. H. Fischer for drawing tungsten filaments. (Page 398.)

THE Oxford Corporation are recommended to accept a proposal for the adoption of petrol-electric tramcars. Colonel Sir H. A. Yorke has retired from the post of Chief Inspecting Officer of Railways for the Board of Trade. The single-phase electric railway through the Loetschberg Tunnel was inaugurated last week. (Page 399.)

THE appeals against the result of the arbitration between the Post Office and the National Telephone Company have been withdrawn, and a compromise has been arranged. Although the terms were not announced in Court, we are able to state that the sum realised by the National Telephone Company will enable the deferred shares to be paid off in full, and it is estimated that there will then be a further surplus of considerably over £100,000 for distribution. (Page 399.)

THE Aberdeen Borough Electrical Engineer has been awarded £250 damages in a libel action.—An interesting charge of "stealing" electricity has been heard at Weston-super-Mare.—The L.C.C. is not satisfied with the offers it has received for the purchase of the Musgrave steam engines at Greenwich.—Last year's profits from the Brighton Electricity undertaking have been transferred to relief of rates, despite the advice of the Borough Electrical Engineer.—There was a profit of £8,477 upon the Bradford Electricity undertaking for last year, £6,248 at Sunderland, and £7,725 at Hull. The Stalybridge Joint undertaking showed a loss of £9,124. (Page 399.)

TWO 5,000-kw. turbo-generators and two cooling towers are required at Birmingham, mains at Leeds, incandescent lamps by the L.C.C., generating plant at Roscrea and Mile End, motor-generator at Sunderland, and sub-station plant at Hackney. Extensions

are contemplated as follows:—Ipswich, £33,500; Keighley, £6,800; Hebden Bridge, £3,250. (Page 399.)

THE scheme for the reconstruction of Messrs. Crompton & Co. has been successfully carried through. Very satisfactory reports have been issued by Waygood & Co. and the Aron Meter Co. (Page 400.)

**Osram Lamp Patents.**—Before Mr. Justice Warrington in the Chancery Division of the High Courts on Tuesday, judgment was given with costs in default of defence against Messrs. David Smith and Co. for infringement of the Osram Lamp Patents.

**The "B. & K." Restaurant.**—This restaurant, in which the cooking is all carried out electrically, is now in thorough working order, and a wide variety of appetising dishes can always be obtained. Luncheons, teas, and dinners are served at the usual hours, as well as coffee, chocolate, &c., during the forenoon. The restaurant is situated at 254 to 260 Earl's Court Road, S.W., and is the property of the Brompton and Kensington Electricity Supply Co., Ltd. It was fully described in *ELECTRICAL ENGINEERING*, May 8th, p. 255.

**Action for Wrongful Dismissal.**—An action for wrongful dismissal brought by Major Glyn (Managing Director of Holophane, Ltd.) against the company has just been heard by Mr. Justice Bailhache and a special jury in the King's Bench Division. The jury, after deliberating for less than a minute on the evidence, which had lasted three days, found a verdict for Major Glyn for £400 damages, as being the equivalent of six months' notice. While Major Glyn was managing the Holophane business, they felt the competition of similar fittings made in Germany and sold under the name "Dilux." This business was bought up by the Holophane Company, and the fittings sold under the name of "Holophane." This resulted in Major Glyn's dismissal, which, as stated above, the jury found was not justified. Evidence by Professor S. P. Thompson, Mr. Haydn Harrison, Mr. C. C. Paterson, and others showed that the "Dilux" glass was slightly heavier, that the absorption of light was slightly less, but that the distribution was not quite so good as the "Holophane."

**Electrical Trades' Benevolent Institution.**—A letter from Mr. Justus Eck, Chairman of the Committee of this Institution, reaches us as we go to Press. Mr. Eck writes:—"On my return from Australasia I was much gratified to hear of Mr. G. Byng's splendid offer, namely, to give £100 to the funds of the Electrical Trades' Benevolent Institution if £1,000 could be raised in individual amounts of not less than £50 each, before July 16th, 1913. In view of the large number of wealthy persons connected with and benefiting by the electrical industry, however, I am surprised to find that over two months have gone by and the donations are still short of the amount by £250. The calls on the Institution for grants for temporary relief are increasing steadily, although the Committee has fortunately been able to keep the sum of the grants down to a low figure by their success in obtaining employment for most of the persons assisted, and no qualified person who has applied for assistance has failed to receive it."

**British Association.**—The preliminary programme for the British Association meeting at Birmingham, from September 10th-17th next, has now been issued. Among the papers arranged for Section G (Engineering) are "Some Effects of Atmospheric Conditions on Wireless Signals," by Prof. E. W. Marchant, and "The Nature of the Electromagnetic Waves employed in Radio-telegraphy, and the Mode of their Propagation," by Prof. G. W. O. Howe. Prof. Gisbert Kapp's Presidential Address, it may also be assumed, will contain some matters of electrical interest; whilst there is also to be a demonstration of electric cooking appliances. The annual report of the Committee on Gaseous Explosions will also be presented. In Section A (Mathematics and Physics) the following will be presented:—Presidential Address, by Dr. H. F. Baker; "Nature of X-Rays," by Prof. Barkla; Discussion on Radiation; "Lightning and Protection from It," by Sir J. Larmor; "A New Method of Starting a Mercury Vapour Lamp" and "A New Method of Sealing Electrical Conductors through Glass," by Mr. J. S. Anderson; "A Direct Method of Measuring Magnetic Susceptibility and Instruments for this Purpose," by Mr. W. H. F. Murdoch. There will also be a paper by Prof. E. Rutherford. In Section B (Chemistry) there will be a discussion on the Future of British Fuel, and a paper on the effect of impurities in commercial copper, by Mr. F. Johnson. In Section F (Economic Science and Statistics) there will be a discussion on Canals and Inland Waterways.

### The London Electrical Engineers.

(To-Day) THURSDAY, JULY 3RD.—C. Company. FRIDAY, JULY 4TH.—D. Company. Infantry Drill, 7 to 9 p.m. Technical Instruction for all members of the Sixth Rate and for all Candidates for Higher Rating, 7 to 9 p.m.

SAURDAY, JULY 5TH.—Royal Review.

MONDAY, JULY 7TH till FRIDAY, JULY 11TH. Headquarters open 10 a.m. till 4 p.m.

SAURDAY, JULY 12TH. Headquarters open 10 a.m. till noon.

## THE NATIONAL PHYSICAL LABORATORY

A LARGE gathering assembled at the National Physical Laboratory on Thursday last on the occasion of the opening of the new buildings of the Laboratory by the Rt. Hon. A. J. Balfour, F.R.S. The ceremony was held in the new building, in which will be constructed a large air channel and other apparatus for aeronautical research, and the chair was taken by Sir Archibald Geikie, P.R.S. (Chairman of the General Board of the Laboratory). A number of distinguished men were on the platform.

Sir A. Geikie in his introductory remarks referred to the growth of the laboratory and the pressing need that had existed for such buildings as the fine new administrative block now completed. Dr. R. T. Glazebrook added a few words apologising for the incomplete state of some of the new buildings, and regretting that they could not be shown fully equipped owing to insufficiency of funds. Lord Rayleigh referred further to the financial situation, saying that the Treasury had only seen fit to supply half of the £30,000 necessary for the new buildings, and if it had not been for a gift from the late Sir William White, the great liberality of the late Sir Julius Wernher and Lady Wernher, and a grant of £5,000 from the Commissioners of the 1851 Exhibition, the scheme could not have been carried out. They were still in want of adequate equipment. Some people had regretted that a larger proportion of the work of the laboratory could not have been devoted to pure science, apart from its applications, but unfortunately this was also a matter of funds, and perhaps the future would put them in a more fortunate position in this respect.

Mr. Balfour, in rising to declare the new buildings open, dealt with the general question of the *raison d'être* of the laboratory. It had often been asked why its work could not be left to private enterprise, and if of vital interest to the manufacturers, left to the industries themselves; and whether the work of standardisation and testing was really so important as to justify the spending of vast sums of public money. With regard to the latter question, measurement was the life-blood of physical science, although many things, such as life itself, could not be measured, and lay at the root of all its applications to practice. Such means of measurement as were provided at the National Physical Laboratory were not only desirable, but if neglected would inevitably cause this country to fall behind. In answer to his first question, it was of great advantage, both to the manufacturer and to the purchaser, to have an independent authority to appeal to, and it was an economy of resources to have a central place to which all manufacturers could come on an equal footing. He shared Lord Rayleigh's regret that a larger proportion of the labours of the laboratory could not have been devoted to abstract scientific investigation. It was to the labours of men working for purely scientific ends that mankind would be most indebted in the future. He hoped that this truth would sink into the public mind and be reflected in a different attitude on the part of those responsible for public expenditure.

Colonel Seely, in proposing a vote of thanks to Mr. Balfour, said that if life could not be measured by science, it could be saved by science. The investigations of the laboratory into the problems of aeronautics had already elucidated concrete facts that had undoubtedly saved the lives of many brave men. He concluded with a well-deserved eulogy of Mr. Balfour's abilities, which elicited a modest reply. The proceedings concluded with a vote of thanks to the Chairman.

The visitors then proceeded to an inspection of the new buildings, which include a central block with ample accommodation for administrative offices, library and lecture room, a north wing for dealing with the reception and despatch of instruments and materials sent in for test, and a south wing for the optics laboratories, to which some of the work formerly carried out at Kew is being transferred. The buildings form the completion of a scheme initiated in 1909 at an estimated cost of £30,000, to which the Treasury contributed £15,000. In 1910 the late Sir Julius Wernher gave £10,000 for the metallurgy building, and some additional cost in its erection was defrayed by Lady Wernher. The building fund was completed by a grant of £5,000 by the Commissioners of the 1851 Exhibition, and £4,000 has been given by the Drapers' Company to found a library in memory of Sir William White. Further funds are still needed to provide equipment. The various other departments were inspected by parties of visitors, and while tea was partaken of on the lawn the interest was added to by the passage of an aeroplane over the grounds.

The Annual Report of the National Physical Laboratory records a large amount of work accomplished in its various departments during 1912, as well as work in co-operation with other bodies.

With regard to the work of electrical interest, Mr. F. E. Smith, in the Physics Department, has nearly completed the measurements necessary to determine the absolute value of the resistance of the international ohm, and his report indicates the high order of accuracy which may be expected. Fourteen new mercury-resistance standards have been constructed; of these five were for the Japanese Government. The value of the international ohm, as found from the old tubes, agrees with that obtained from the new tubes just set up within 1 part in 100,000. The Laboratory standards of resistance have been again compared with those of the Bureau of Standards, the Reichsanstalt, and the Laboratoire Central d'Electricité. The maximum difference is 11 parts in 1,000,000; the Laboratory and the Reichsanstalt agree within 1 part in 1,000,000. The value found at the Bureau of Standards was 1 part in 100,000 greater. During the year, Mr. Campbell communicated to the Royal Society an interesting account of a determination of the ohm by two novel methods, using alternating-current and resistances of considerable value.

A large amount of general testing has been done, including 2,852 tests, and investigation has been prosecuted into power factors of condensers and change of capacity with frequency, wave-meter testing and magnetic testing apparatus. A good deal of new apparatus has also been set up. In the photometric division, the most important researches have been the determination of the candle power of a set of twenty-four tungsten lamps running at 1.5 watts per candle, an investiga-

tion for the Board of Trade into the visibility of ships' lights, and a large number of tests for the Engineering Standards Committee on metallic filament lamps. These are intended to form the basis of a specification by the Committee. Mr. Paterson has become Secretary of a sub-committee appointed to formulate proposals for the reconstitution of the International Photometric Commission, which will, it is hoped, be able to extend its valuable work in connection with problems of photometry and illumination. Another series of investigations for the same Committee has been on the heating of lamp sockets, while much information has been obtained for the Admiralty on the dielectric properties of ebonite and mica. Mr. Melsom has carried out some valuable investigations for the Institution of Electrical Engineers into the heating of flexible cords and cables, while Mr. Rayner read a Paper before the Institution, summarising his work on high-voltage tests and dielectric loss in insulating materials. In the thermometry division, the research work during the latter part of the year has suffered on account of Dr. Harker's regrettable illness. Earlier in the year an important Paper dealing with the discharge of electricity from matter at a high temperature was presented to the Royal Society by Dr. Harker and Dr. Kaye.

Among the work proposed for the current year may be mentioned the investigation on the magnetic testing of rods and strips, including magnet-steel tests, and incidentally the more accurate determination of the areas of search coils; while in connection with the Research Committee of the Institution of Electrical Engineers, some experiments on the steel most suitable for magnets may be undertaken.

## ELECTRICITY IN FACTORIES AND WORKSHOPS

THE Annual Report of the Chief Inspector of Factories and Workshops for 1912, which has just been issued, contains both in the sectional reports and that of Mr. G. S. Ram, the Electrical Inspector, many references to electrical working.

### ELECTRICAL ACCIDENTS.

Mr. Ram's report records 334 non-electrical (including 11 fatalities) and 58 electrical accidents (four of them fatal) at public supply stations, and 37 non-electrical and 16 electrical non-fatal accidents at other stations. The non-electrical accidents are more by 25 per cent. than in the previous year, but the electrical accidents, both fatal and non-fatal, are the same in number. The large proportion (27) due to working at live switchboards, &c., provokes the remark that risks are often taken unnecessarily by engineers and attendants familiar with the dangers. This is fully borne out by the details of the three fatal cases under this heading. The other fatal electrical accident was due to a man walking in the dark into a cable which was under test in the yard of a substation.

The electrical accidents reported at factories other than electrical stations were 283 in number, of which 15 were fatal, and are classified as follows: Arcing of switches, 23; arcing of fuses, 8; shock or burns from fuses when replacing fuse-wires, 27; portable apparatus, connectors and flexible wires, 61; unprotected conductors, switches, terminals, fuses, &c., 27 (one fatal); working on or near live conductors: skilled persons, 32; unskilled persons, 33 (five fatal); miscellaneous accidents in electrical manufacturing and repair works—mostly in testing operations, 32; adjusting brushes and cleaning commutators, and flashing at commutators, 9; miscellaneous, 31 (nine fatal).

Ten of the cases of arcing of switches were due to switching on motors with the starting resistance cut out. Of the accidents due to the use of portable apparatus, half the total were due to damaged flexible conductors. In one case the fusing of the flexible to a portable lamp set fire to petrol in a garage. Nineteen accidents due to improperly constructed connectors, and eight to improperly constructed hand lamps would have been avoided by following Mr. Ram's recommendations in previous reports. The fatal case due to unprotected conductors occurred to a lad in touching live parts (460 volts D.C.) of a controller, the cover of which had been left off. Most of the accidents due to skilled persons working on line conductors could, in Mr. Ram's opinion, have been avoided, as the work need not have been done whilst the conductors were live. The five fatal accidents under this heading occurred to "unskilled" persons. Two were to labourers working on overhead cranes, two to men painting transmission line poles when they thought the line was dead, and one to an assistant commencing work before

receiving instructions. The accidents in testing departments were less than usual. Among the nine miscellaneous fatalities; one was due to the very usual cause of a man receiving a shock from foot to foot while walking over electrically-charged ground. Five occurred in connection with cranes, one was caused by disused wires which were still live, and in another case a man working near an electric lift under erection did not know the gear was live. One accident was due to breakage of an overhead wire during a gale.

Three switchboard fires are reported in public supply stations. Mr. Ram recapitulates the circumstances, and remarks that in all three cases it was the covering of the cables that burned and spread the fire, and although some of the cables were in so-called "fireproof" composition tubes, these appear to have been of little, if any, use in checking the spread of the fire. That where the cables are in a covered trench or under a ceiling or roof, they are most readily attacked, he continues, has been further clearly demonstrated in the case of a fourth station fire which has occurred since the period covered by this report. In this last case the cables were in a subway some six or seven feet in height, and were laid on insulators on racks on each side of the gangway. All the cables within about two feet of the roof of the subway had their insulation completely burned off, but those nearer the ground were practically undamaged. In many of the older stations the cables and wires behind the switchboards and in cable trenches and subways are hopelessly mixed up, so that should a fire be started at any point it would be impossible to prevent it from rapidly spreading and involving the whole. It is a common practice in electrical stations for the cables to be taken from trenches or subways up the wall of the building to the switchboard gallery, the floor of the gallery being cut away, leaving a permanent opening some 12 inches wide all along for the cables to pass through. Two of these fires show the danger of this opening in the floor by allowing the fire to pass upwards and involving the switchboards in the gallery or room above. So long as cables with inflammable insulation are used in electrical stations, it is obvious that some safer system of isolating and protecting them is necessary if the possibility of such disasters is to be prevented. There are no doubt difficulties in many stations on account of the large number of cables which have to be accommodated, but it might be practicable in many cases to separate the cables in channels of brick or stoneware in such a way as would prevent the spreading of a fire from cable to cable. The small wires for instruments, regulating resistances, &c., are often a source of danger, being poorly insulated and looped about anyhow at the backs of the switchboards. It is generally recognised that inflammable woodwork, particularly soft wood, should not enter into the construction of switch-

boards, yet I recently found a new high-tension three-phase switchboard in a public supply generating station practically enclosed in woodwork; the bus-bars were just below a match-board ceiling, and the whole passage-way at the back of the open-fronted cells was enclosed by deal boarding. Whilst there has been a very great advance in the design of high-tension switchboards during the last few years, the same attention has not been given to the design of direct-current medium-pressure boards. These switchboards are commonly arranged so that it is impossible to do any work upon them without danger of making a short circuit. Many of the short circuits due to men working on the live conductors have been between one conductor and the earthed framework. There is nothing impracticable in protecting the framework by slate or other suitable material and protecting bolt heads on the front of the panels in such a way as to overcome this danger, or in putting more divisions between adjacent conductors of opposite polarity, and the extra cost involved would be well repaid by the increased security against accident and breakdown. Again, in comparatively few stations are insulated spanners or special tools provided for use on live switchboards. There are still many examples of switches and switch fuses not arranged "so that the hand cannot inadvertently touch live metal."

Of the above 18 fatalities directly due to electric shock, five were on high-pressure or extra-high pressure alternating-current systems. Ten were on medium-pressure alternating systems; six of these were shock to earth on three-phase systems of which the pressure between phases was 440 volts or less, and as the neutral point was earthed in probably each case, the pressure received would not exceed 250 volts in any instance. One was from a 200-volt single-phase system. Of the two on direct-current systems, one was on a 460-volt three-wire system, but not having the middle wire earthed, and the other on a 220 volt two-wire system.

In only nine cases is it clear that any attempt was made to resuscitate the victim by means of artificial respiration. Mr. Ram emphasises the importance of not only applying artificial respiration in every case, but continuing it a sufficiently long time, and quotes medical opinion to the effect that "practically every case can be revived, and most of these will make a complete recovery if first-aid is promptly forthcoming and properly applied."

#### LEAD POISONING IN ACCUMULATOR FACTORIES.

The reports of the sectional inspectors of the different localities, as well as that of the medical inspector, bring out the regrettable fact that there has been an increase in the proportion of lead-poisoning cases in accumulator factories, due principally to the inhaling of dust and fumes. This is particularly the case in the South-Eastern District, where, in East London alone, there were 13 cases as against a total of 19 for the whole of the previous six years. The more complete provision of exhaust ventilation is being pressed for as a remedy.

#### LIGHTING.

Conditions of illumination are dealt with to an increased extent by factory inspectors, and a special report is given this year on the artificial lighting of iron foundries by Mr. D. R. Wilson. The dull colour of the floor and surroundings, and the frequent presence of dust and smoke, render a high degree of illumination necessary, and shadows are particularly undesirable. The method recommended is by powerful units fixed as high as possible above the floor, and spaced comparatively close together. Observations of the illumination in a number of actual cases are tabulated. The investigation appears to show that the illumination received on a horizontal plane one foot above the floor level does not fall below 0.5 foot-candle in well-lighted iron foundries, 0.3-0.4 in fairly well-lighted, 0.2-0.3 in moderately, 0.1-0.2 in poorly, and is below 0.1 in badly-lighted foundries. It would seem, therefore, that the lighting cannot be deemed to be adequate unless the illumination received on a horizontal plane one foot above the floor level is not less than one-third of a foot-candle over any part in which work is being carried on or over which any person is liable to pass.

Several of the sectional inspectors refer to illumination, and Mr. Skinner (Bristol) in particular is encouraging the avoidance of glare by frosted lamps and suitable shades. In some cases, such as Leicester, the successful introduction of mercury vapour lamps is reported, and from Londonderry the inspector writes:—"In one large factory 70 16-c.p. metal filament lamps were replaced by four mercury vapour lamps placed under the ceiling. Although, owing to the light being more concentrated with these lamps, the candle-power required to give the necessary illumination is greater, it has

been found that the light is much softer on the eyes of the workers and that headache is in consequence less frequent amongst the girls than it used to be.

#### MISCELLANEOUS.

The report of the principal lady inspector calls attention to the conditions in incandescent lamp factories. In some of the sealing-in and exhausting departments, where a large amount of gas is continually burnt, unduly high temperatures were found. The effect of certain operations on the eyesight of the workers has also been inquired into, but complaints of eye-strain, though sometimes met with, were not common. Glasses of smoked or blue glass are sometimes provided and worn for the testing work. In the manufacture of arc lamps, the occurrence of electrical ophthalmia among the men was met with, but there seems no evidence of anything resembling this among those exposed to the weaker light of incandescent lamps, nor of any gradually progressive injury to the sight. The Diesel engine explosion at Bray is referred to in the special report on dangerous trades, and, after discussing some other similar cases, it is remarked that the danger of explosion is considerably accentuated if compressed oxygen is used for the purpose of starting any type of internal combustion engines.

### OSRAM LAMPS ON THE JUNGFRAU RAILWAY

SOME time ago we chronicled the fact that electric light had been installed on the Jungfrau Mountain Railway in Switzerland, and in view of this we think that the accompanying illustration may prove of considerable interest to our readers. The highest railway station in the world, situated 3475 metres above the sea level, on the Jungfrau electric mountain railway, is lighted by means of Osram drawn wire lamps.

THE JUNGFRAU RAILWAY.

The station having been satisfactorily lighted, the next step was the application of these lamps to the illumination of the trains. The above illustration shows one of the trains with its three-phase rack locomotive. The nature of the work is a fine illustration of the way in which Osram lamps are able to withstand the jolts and jars.

### MAZDA AUTOMOBILE LAMPS

A FOLDER dealing with various types and sizes of Mazda drawn wire automobile lamps has been issued recently by the British Thomson-Houston Co. (77 Upper Thames Street, E.C.). These lamps are not merely standard lamps made in

MAZDA HEADLAMP.

small sizes, but have been specially designed for the peculiar conditions of motor-car service. They are tremendously strong, and are not affected in any way by jolting or vibration, and they are between three and four times as efficient as carbon filament lamps. The lamps include headlight lamps, side and rearlight lamps, and tubular and festoon lamps for interior lighting. In each class the filaments have been constructed with the object of giving the most suitable distribution of light for the particular purpose. The headlight lamp, for example, has a very small helical coil filament approaching as nearly as possible the theoretical point source, so that when used in a parabolic reflector all the light is thrown forward in a parallel beam. They are supplied in voltages from 4 to 12, and in candle-powers from 6 to 50. Side and rearlight lamps are made in voltages from 2 to 12, and in candle-powers from 1 to 12, while the tubular and festoon lamps range from 2 to 12 volts and from 1 to 8 candle-power.

Copper (electrolytic wire bars), £69 5s. per ton of 2,240 lbs.; aluminium (electrolytic wire bars), £90 10s. per ton of 2,240 lbs.

This price of copper is about 5 per cent. higher than the average price for the last 15 years, during which period it has fluctuated between £54 and £122 per ton. On the other hand, aluminium has fallen from about £200 per ton to the above figure, after making a somewhat artificial drop to £60.

The author then gave tables comparing the costs of aluminium and copper cables, all designed to comply with the Engineering Standards Committee's Specification of March, 1910.

For 0.1 sq. in. 3-core medium pressure copper cables, and the equivalent aluminium cables (1.66 sq. in.) he found that the aluminium cables is the cheaper in plain lead-sheathed cables whenever aluminium wire bars are less than £22 per ton above the price of copper bars; in single-wire armoured cables whenever aluminium wire bars are less than £10 per ton above the price of copper bars; and in double-wire armoured cables, only when aluminium wire bars are lower in price than copper bars. In all cases, however, the percentage saving is small.

It is for low- and medium-pressure D.-C. cables that the chief economy is shown when using aluminium. A comparison made by Mr. Welbourn between a 0.30 sq. in. copper single conductor paper-insulated lead-sheathed cable and the equivalent 0.50 sq. in. aluminium cable, both being built to comply with the Home Office Rules, shows that, for a plain lead-sheathed cable, there is a saving of 8 per cent. when aluminium bars are £22 per ton greater than copper, and that this saving will actually become 17½ per cent. if at any time aluminium is £10 per ton cheaper than copper. With single-wire armoured cables the saving is 4½ per cent. when aluminium is £10 per ton above the price of copper, but with double-wire armoured cable of this size, the saving which can be effected by aluminium, even when it is £10 per ton cheaper than copper, would only be 4½ per cent. Comparisons of bitumen-insulated D.-C. cables give very similar results. The author also pointed out that with larger sizes of unarmoured D.-C. cables the saving by using aluminium is greater, and stated also that unarmoured concentric and triple concentric aluminium cables for pressures up to 650 volts usually show a considerable saving over the equivalent copper cables.

The remainder of the Paper dealt with Overhead Lines and Jointing, and we hope to publish this portion, together with the discussion, in our next issue.

## ELECTRIC MINING AND METALLURGICAL PATENTS OF JUNE

### Mining.

THE only patent specification of particular interest to mining electrical engineers published during the past month is No. 14,494/12 by J. H. Hoadley (President of the Consolidated Coal and Iron Co., U.S.A.). The specification covers a method of mining coal which consists in comminuting the coal as it is removed from the seam by continuously moving fluids, introducing it into a producer, and then conveying the gas out of the mine through pipes.

### Metallurgical.

In specification No. 11,643/12, by W. E. Gibbs (Birkenhead), is described a process for extracting tin from its ores and slags by the electrolysis of the fused mass (which is heated in a reverberating furnace). The cathode consists of a layer of molten tin and is connected by a channel with a smaller vessel containing the liquid tin. After the tin has been extracted a similar process is carried on with separate cathodes, for the extraction of any tungsten, titanium, and molybdenum present. Specification No. 16,275/12 by A. Hiorth (Norway) deals with the direct production of iron and steel from the ore. Purified gases rich in carbon monoxide and nitrogen compounds are forced with air or oxygen into the upper part of the charge of a shaft furnace, and also through an electric arc furnace into a hearth furnace directly connected with and taking up the molten mass from the shaft furnace. The charge consists of ore with or without a slight addition of carbonaceous material. The gas from the top of the shaft furnace may be supplied to a gas producer for obtaining the necessary gases. They may be preheated by being passed through a jacket surrounding the shaft furnace.

## GENERAL REGULATIONS UNDER THE COAL MINES ACT

LORD MERSEY, sitting as referee, has had the draft general regulations made by the Home Office under the Coal Mines Act, 1911, and the objections to them, before him from June 17th to 27th. Few points of special interest to mining electrical engineers were raised as the electrical regulations have already been settled (ELECTRICAL ENGINEERING, February 6th, p. 74). The objections lodged to the General Regulations were also announced in ELECTRICAL ENGINEERING for May 1st, p. 244.

When regulation No. 68, under the heading "Use of Electric Lamps [Section 32]" came up for discussion, Sir T. Ratcliffe Ellis, who represented the Mining Association and the Colliery Managers' Association, asked that the words "other than Locked Safety Lamps" might be inserted in the heading, as this was what was intended. This was allowed. The regulation itself as drafted did not allow electric lamps within 300 yards of the coal face. Amendments were proposed by Sir T. Ratcliffe Ellis to give permission to use incandescent electric lamps in any part of a mine where the percentage of inflammable gas in the general body of the air in that place did not exceed 1½. In support of this it was pointed out that especially on haulage roads (where the greater number of accidents occur) it is very necessary to have a good light. Witnesses, including Mr. W. C. Blackett (President, North of England Institute of Mining and Mechanical Engineers) said that these enclosed lamps were safer than safety lamps. Mr. Blackett also said that there was less likelihood of an explosion resulting from the fracture of an incandescent electric lamp in an explosive mixture than a safety lamp. Mr. Redmayne (H.M. Chief Inspector of Mines) argued that in most cases it was dangerous to take these lamps nearer the coal face than 300 yards because falls of roof were more frequent, and because blowers or temporary blowers of gas would not allow time for the current to be switched off. He suggested that electric safety lamps could be used. A safety lamp giving 7 c.p. had, he said, recently been submitted to the Home Office for tests. In few cases were the main haulage roads carried so near the face. Evidence was given of the existence of such cases and also of pumps and other electrical machinery within that distance which were lighted by electric lamps.

Mr. Smillie (President of the Miners' Federation) admitted that the men had an "honest fear of electricity" for any purpose underground. They did not like electric safety lamps because there was no means of detecting the presence of inflammable gas. Eventually Lord Mersey said he must allow the regulation as drafted, leaving those cases which he was sure existed where it would be right to permit the use of electric lamps close to the face to be dealt with by special rules. He hoped he was right in the attitude he took up, but did not feel sure about it.

Other important regulations were those relating to the proposed substitution of a uniform code of signals for signalling for both winding and haulage. Regulation 82, relating to winding, was finally amended, and it was made necessary for the installation in every case of "an appliance which shall automatically indicate the signal to the winding engineman until the signal is complied with." This regulation does not come into force till July 1st, 1914. It was not made necessary for an indicator to be installed for haulage, but evidence was given by several mine managers that they used electric signalling systems in which each signal rang the bell at the sending station as well as at every other station in the circuit, so that all stations knew what signals were being given. It was argued that with this system it was not necessary to repeat the signals as required by the new regulations, as if one bell rang it followed that all the others did. The regulation relating to repeating all signals received was, however, passed. Regulation 91, relating to the installation of telephones, was also amended on the application of Sir T. Ratcliffe-Ellis, and it now reads thus:—"Where in any mine not being a small mine the distance of the main haulage from the shaft exceeds 1,000 yards, efficient means of telephonic communication shall be provided and maintained between the end of the main haulage and the pit bottom, and thence to the surface. This regulation shall not apply to mines of stratified ironstone in the Cleveland district or to mines in any other district, as respects which the Secretary of State is satisfied that similar conditions prevail."

## ELECTRICITY IN MINING

THIS is the title of a handsome volume, with nearly two hundred illustrations, which has been compiled by Siemens Brothers Dynamo Works, Ltd., and is published by C. Griffin & Co. at the price of 10s. 6d. net. The first of its twenty chapters deals generally with the object and scope of electrical mining installations, and this is followed by selected descriptions of large distribution systems in various parts of the world, including the Cambrian Colliery group and the extensive system of the Powell Duffryn Steam Coal Co. in South Wales, the interlinked power companies of the north-east coast, and some large German systems. After a few words on choice of pressure and system, the plant is

studied more in detail, and reciprocating engines, steam turbines, gas engines, Diesel engines, and water-driven generating plant are treated successively with a wealth of illustration of actual examples. A few illustrations indicate the different types of switchgear that may be employed in generating stations, including a particularly neat compromise between the desk board and the pillar for remote control. The subject of transmission is then completed by details of typical examples of transformers, cables, and overhead lines. After thus indicating how electric power is supplied to collieries, its uses at the pit are studied in more detail. Some forty pages, containing as many illustrations, give us an excellent idea of modern practice in electric winding engines, both as driven by three-phase induction or series commutator motors, and by the Ward-Leonard continuous-current system. Not the least interesting part is that devoted to the load equalisation, and the battery system, with Pirani type of booster, is described, as well as the world-famed Siemens-Ilgner flywheel system. Examples of such installations are taken from Germany, Austria, Holland, France, and South Wales, including some remarkable plants where the actual winder is mounted on the headgear right over the shaft. Electric pumping plant is also treated by the aid of numerous examples, embracing reciprocating and centrifugal apparatus, the latter including vertical shaft direct-coupled sets for sinking work. The conditions to be met by fan motors and air compressors are then discussed, and among the examples the interesting Rand turbo-compressor station at Robinson Deep is illustrated. Other classes of apparatus dealt with are underground haulages and hoists, and such auxiliary in-by machines as portable air compressors, pumping sets and fans. The field of usefulness of the electric locomotive, both underground and on the surface, is then discussed, and among the examples illustrated is the traction system of the Harton Coal Co. A few examples of electrically-driven coal washeries, briquette factories, &c., are next illustrated, and a few words are added on machinery specially designed for transport in foreign lands. The next chapter puts forward the claims of the electric rock-drill, of which the Siemens firms were among the pioneers, and then we come to the all-important subject of switchgears for use below ground, and flame-proof motors and apparatus generally. Finally, electric signalling systems for mines and shot-firing apparatus are dealt with, and we lay down the book with our ideas widened as to the vast store of experience which the Siemens companies have to draw upon, the completeness of the study their engineers have given to the subject, and the success which is attending their efforts.

**Electric Locomotives at Collieries.**—The Harton Coal Co. are further extending their electrically-worked railways between their collieries in the South Shields district, and have ordered a new eight-wheeled, 140-ton locomotive from the A.E.G. Electric Co. This locomotive will be 35 ft. in length, and will be carried upon two four-wheeled bogies equipped with four motors of 70 h.p. each. It will be worked by direct current at 500 to 550 volts, supplied by an overhead line. The bogie-wheel base will be 5 ft. 4 in., and the centres of bogies will be placed 18 ft. apart. The locomotive will have a speed of eight miles an hour, and a tractive effort of 12,200 lb.

**Production of Electrical Steel.**—There are at the present time 14 plants in the United States equipped with electric furnaces, while five other contracts have been let, says *The Iron Age* (New York). From 1909 till 1911 the following countries show considerable continuous increases in the production of electric steel: Germany and Luxemburg, Austria-Hungary, France, and Sweden; but the United States shows a falling off in the output for 1910 to 1911 of over 44 per cent. In America the practice is generally to take the steel to the electric furnaces in a molten condition from Bessemer converters or open-hearth furnaces. On the Continent, and to some extent also in this country, cold metal is usually charged into the furnaces and melted by electricity. In Italy there were four electric furnaces in operation in 1911, two in 1910, and five in 1909. In Sweden the numbers were 13, 12, and 11 for the three years, and in Germany 15 in 1911 and 13 in 1910, while in France the number in operation in 1910 was 21, compared with 12 in 1909 and seven in 1908. In 1911 almost half the world's output of 128,510 tons was supplied by Germany, while Sweden accounted for 2,034 tons only.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,345.

"HARMONIC" has made up a wireless telegraph installation, and he finds that if he simply taps a few feet of flex on one side of any lamp in his electric lighting installation, he can receive signals from a number of wireless stations, and some of these are exceedingly clear. He does this when the lamp is actually alight, and he also finds that he still gets signals when the main fuses are out, but in this case he believes belonging to one station only. How is this explained?

(Replies must be received not later than first post, July 10th.)

### ANSWERS TO No. 1,343.

There are twelve three-core lead and armoured cables suspended in a culvert. Ten are for three-phase current; two are for direct current. I wish to test by some simple method in the culvert, without cutting the cables, to ascertain which are carrying three-phase current and direct current respectively, which are dead and which are alive, but not delivering current. There are no link boxes. The apparatus used must be such that one man can carry it. How can this be done?—R. S.

The conditions of the question make the problem rather a difficult one, and it is questionable whether there is any way to obtain the information with any degree of certainty in the manner required by the questioner. Few replies have therefore been received. An award of 10s. has been made to J. F. ROMER, who writes as below. Too much reliance, however, should not be placed upon the test, as methods relying upon want of balance in three-phase circuits, and slight inductive effects, are often liable to give misleading results.

When a lead-covered or armoured cable is carrying an alternating current there is usually an appreciable potential difference between different points on the metal covering, and if any two points are connected by a telephone as a shunt, a characteristic hum will be heard corresponding to the frequency. In order to carry out this test, a telephone of about 50 ohms resistance and two long flexible wires are required. Select a length of the cable which is not touching any conductor, and having bared both ends of the two flexibles wind one end of each flexible round the cable sheathing, and connect the two other ends to the telephone terminals as shown in the diagram. The distance A should be made as great as possible.

On three-core cables carrying three-phase current, if the phases were exactly balanced no sound might be heard, as

the induced E.M.F.'s tend to neutralise each other, but the phases are usually sufficiently out of balance for this test to be used. If the cables are sufficiently slack so that a temporary U-bend can be made, a much better result will be obtained by using a search coil of about 50 turns of No. 20 S.W.G. cotton-covered wire wound into a coil about a foot in diameter. This is connected to the telephone, and the coil held near the U-bend and parallel to it. Both the above methods require a large current to be flowing in the cables.

After testing all the cables in the above manner, those which produce no sound in the telephone should be re-tested

with the search coil connected to a sensitive galvanometer of about 20 ohms resistance (a Unipivot instrument would do). On jerking the search coil about in front of the U-bend a deflection will be produced on the galvanometer if continuous current is flowing in the cable.

There is no method of distinguishing between cables which are dead and those which are alive, but not carrying current, without cutting the cables, and since the metal covering is earthed a leakage test cannot be used.

## ANSWERS TO CORRESPONDENTS

**INTERESTED.**—The conductivity of your armouring is ample; that of the copper sheath alone is considerably more than the value required by the regulations, which is half that of one conductor.

## CATALOGUES, PAMPHLETS, &c., RECEIVED

**ELECTRIC PORTABLE TOOLS, &c.**—A collection of leaflets from the Westminster Tool and Electric Co. (Suffolk House, Lawrence Pountney Hill, Cannon Street, E.C.) gives particulars of a variety of patterns of portable electric-driven drills, pillar drills, magnetic holding on devices, chucks and fixing plates, electric grinders, and other convenient portable tools.

**COLLIERY CABLES.**—The Paper read a short time ago by Mr. W. T. Anderson before the Manchester Geological and Mining Society on Colliery Cables (*ELECTRICAL ENGINEERING*, March 6th, p. 132), is now available complete with the discussion. Messrs. W. T. Glover and Co., Ltd. (Trafford Park, Manchester), will be glad to supply a copy to any of our readers who are interested in this subject.

**GLOVER'S ALMANAC.**—This well-known collection of humour, wisdom, and art makes its twelfth appearance, as usual, in the middle of the year. The contents appear to be well up to the high average already established, and we look forward to enjoying each daily slip in due sequence.

**Air Filtration.**—A clerical error occurred in our report of Mr. J. Shepherd's remarks during the discussion on Air Filtration, published last week (p. 376). The example he gave was of a 10,000-kw. generator, and not of a 1,000-kw. generator. Our readers will doubtless already have divined this from the context; and, in fact, the machine is actually mentioned as a 10,000 kw. machine lower down in the report.

**Conversazione of the Institution of Electrical Engineers.**—The annual conversazione of the Institution of Electrical Engineers was held on Thursday last at the Natural History Museum, South Kensington. About 1,200 members and guests were received by the President, Mr. W. Duddell, and Mrs. John Smithers and the Council. Enjoyable selections of music were rendered by the String Band of the Royal Engineers in the Central Hall, and the Royal Windsor Glee Singers executed a varied programme of vocal music with the same ability as on previous occasions.

# "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

## Specifications Published June 26th, 1913

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

152/12. **Lighting Gas Lamps.** H. S. COOKE and F. WESTWOOD. To light the lamps on automobiles, a circuit is taken to the lamps from the magneto or ignition coil through a make and break switch, the circuit to each lamp ending in a spark gap over the burner. Two figures.

5,424/12. **Projecting Pictures.** F. DUSSAUD. For projecting pictures from transparent or opaque films, &c., low-pressure incandescent lamps (i.e., below 25 volts) emitting a light less than 30 c.p. at the normal pressure, are subjected to a pressure of 50 to 150 per cent. above their normal pressure, and are supplied with a parabolic reflector or short-focus condenser with a ratio between diameter and focal length of 1.8. It is claimed that the apparatus gives results as good as when one or two hundred times the energy is used in other apparatus. Five figures.

10,576/12. **Detecting Presence of Icebergs, &c.** ADAM HILGER, LTD., and L. BELLINGHAM. A ship is provided with a thermopile or bolometer, which is directed towards the region to be searched. It is connected to indicators through relays actuated by changes in the E.M.F. of the thermopile, or in the resistance of the bolometer due to variations in the radiation of energy to or from the receiver due to the presence of cooler or warmer bodies. Two figures.

12,530/12. **Manufacture of Insulated Wire Coils.** L. FRENKEL. The whole of the operations of varnishing, fibre-covering, baking, &c., are performed while the wire passes from the unwinding drum in its bare condition to the drum on which it arrives in its finished coiled state. The wire is simply made to travel through successive baths, where the desired operations are carried out. One figure.

15,155/12. **Submarine Telegraphy.** E. S. HEURTLEY. Morse signals are sent into the cable by impulses produced by a vibrating contact maker controlled by the sending apparatus, so that the impulses are in all cases fully completed and of equal duration, independently of the contact made by the key. It is arranged that consecutive signals are of opposite sign, and the speed of the contact maker is controlled by electric retardation, mechanical inertia, cams, or by a train of wheels. The duration of the impulses is controlled by a relay, and two messages may be sent through the cable in the same direction at one time, and also code signals may be formed. Five figures.

14,518/12. **Ammeters, Voltmeters, and Wattmeters.** B. T.-H. Co. and A. P. YOUNG. A thin strip of a conductor on one side of a coil is mounted in the narrow air gap of a permanent or electro-magnet. This coil is mounted on light strip conducting springs, so that on the passage of current it is compelled to move bodily across the lines of force. The springs are very flexible in the direction in which motion takes place, but stiff to motion in other directions. The motion is transmitted to the pointer through suitable multiplying gear. Five figures.

16,318/12. **Conduit Continuity Clip.** E. A. EDWARDS (Credenda Conduits Co.). A split tapered sleeve or bush is knurled or roughened externally or internally, and embraces the conduit and enters the adjacent end of a fitting in which it is a tight fit. Four figures.

18,087/12. **Cooling Dynamos and Motors.** SIEMENS DYNAMO WORKS and J. W. HOWARD. A transverse air current is set up between an inner and an outer casing by a fan on the end of the spindle. The inner casing encloses the working parts, and the main frame forms the outer casing, while the former comprises two cup-like shells secured to the stator and the shaft bearings. Two figures.

18,746/12. **Storage Battery Cranes.** B. T.-H. Co. (G.E. Co., U.S.A.). A hoisting jib, which may be locked in the hoisting position, is located at the forward end of a chassis so as to overhang it, and the hoisting gear, consisting of a winding drum, motor, and controller, is situated at the base of the jib, while a propelling motor is located at the back of the chassis and drives the road wheels through chains, and is controlled by a separate controller. The storage battery is also located on the rear platform. Five figures.

29,160/12. **Arc Lamps.** F. R., R. V., and F. BOARDMAN. A multiple carbon arc lamp has a common striking frame for supporting the clutches, a series and an auxiliary shunt solenoid for controlling the movement of the frame and the feed, and a flexible switch arm carried by the striking frame and arranged to momentarily make contact with a fixed arm as the striking frame falls, due to the weakening of the pull due to the series coil. The contact in the shunt-coil circuit is broken by the sudden pull of the shunt solenoid. Two figures.

## Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

**Arc Lamps:** RAILING and ANGOLD, 21,411/12.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** SCHOLES [Insulators for flexibles] 13,401/12.

**Dynamos, Motors, and Transformers:** DÉRI [Commutating devices] 14,236/12; ASHTON [A.C. distribution] 17,386/12; VANDERVELL and MIDGLEY [Self-regulating dynamos] 17,838/12; B. T.-H. Co. [Dynamos] 21,762/12.

**Electrometallurgy:** SOKOLL [Electric welding] 15,216/12.

**Heating:** SIMPEX CONDUITS and WATERHOUSE [Elements] 15,275/12.

**Ignition:** CHARLES [Sparking plugs] 22,387/12; JOHNSON [Sparking plugs] 23,605/12; MASON [Systems] 4,670/13.

**Incandescent Lamps:** B. T.-H. Co. (G. E. Co., U.S.A.) [Joining tungsten to copper] 10,338/12.

**Meters:** BEATHY [Adjusting] 29,566/12.

**Switchgear, Fuses and Fittings:** GOURDON [Swivel joint for fittings] 13,804/12; MARKT [Ceiling roses] 13,865/12; DONOVAN [Starters] 14,036/12; BROADBENT [Starters] 14,088/12; BONNIN [Name plates and pushes] 15,841/12; WINTERHALDER [Automatic cut-outs] 19,164/12; FRENCH B.T.-H. Co. [Regulators for variable speed dynamos] 19,537/12; MOLLETT and EDWARDS [Shade supports] 19,621/12; SIEMENS-SCHUCKERT [Safety device for generators] 28,483/12; FRENCH B.T.-H. Co. [Regulators for variable speed dynamos] 5,020/13.

**Telephony and Telegraphy:** LYONS [Selective receivers] 10,911/12; BLOCK [Telephone disinfectant] 411/13.

**Traction:** COLLINS [Points] 5,703/12; GIBSON, FARMER and READ [Fog signalling] 22,494/12; ALLISON (Wooding Railway Warning Device Co.) [Signalling] 29,238/12.

**Miscellaneous:** J. STONE & Co. and DARKER [Fans] 13,785/12; SIEMENS & HALSKE [Fire alarms] 24,037/12; SIEMENS BROS. (Siemens & Halske) [Medical electrodes] 28,645/12; BROWN [Testing] 178/13; MENZEL and PORDES [Portable battery lamps] 6,673/13.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Dynamos:** GIRARDEAU [High frequency] 12,809/13.

**Incandescent Lamps:** WOLFRAM LAMPEN A.G. [Tungsten alloys] 27,442/12; [Supports for filaments] 12,753/13.

**Miscellaneous:** NATHORST [Magnetic separators] 12,368/13; RENNERFELT [Power transmission] 12,810/13; DECLERE [Silvering of glass] 13,109/13.

The following Amended Specification may now be obtained.

B. T.-H. Co. (G.E. Co., U.S.A.) [Moulded insulator] 6,405/12.

## Opposition entered to Grant of Patents

5,692/12. "Direction" Tell-tales. J. C. CLARKE and CHADBURN'S (SHIP) TELEGRAPH CO. Electrical tell-tale apparatus for indicating speed and direction of marine engines.

9,981/12. C. H. FISCHER. Drawn Tungsten Wires. (ELECTRICAL ENGINEERING, May 8th, p. 264.)

19,014/12. Selective Wireless Call System. F. JAMIESON. (ELECTRICAL ENGINEERING, May 8th, p. 264.)

## Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

**Arc Lamps:** T. L. SCOTT [Suspension] 5,719/08.

**Dynamos, Motors and Transformers:** M. DÉRI [Dynamos and converters] 4,784/00; B. T.-H. Co. (G.E. Co., U.S.A.) [Dynamos] 6,195/06.

**Incandescent Lamps:** B. T.-H. Co. (G.E. Co., U.S.A.) [Metalised filaments] 5,416/08, A.E.G. [Filament holders] 5,610/08.

**Switchgear, Fuses and Fittings:** G. CHARLTON [Switches, meters, &c.] 5,172/01; B. T.-H. Co. (G.E. Co., U.S.A.) [Resistances] 5,415/08.

**Telephony and Telegraphy:** J. H. WILLIAMS [Line tapper] 5,331/07.

**Traction:** B. T.-H. Co. [Magnetic track brakes] 4,881/05; B. T.-H. Co. and B. HORPS [Control in petrol-electric system] 5,671/07; W. L. WISE (C. C. Anthony) [Signalling] 5,729/07; C. E. S. BILL [Overhead conductors] 6,057/07; W. R. SKES [Signalling] 5,489/08.

**Miscellaneous:** L. B. MILLER [Winding induction coils] 5,811/03; C. A. STEVENSON [Lighthouse lamps, &c.] 5,916/07; P. G. TRIQUET [Primary batteries] 5,925/07; J. B. STRUBLE [Lightning arresters] 5,390/08.

## ELECTRIC TRACTION NOTES

The retirement of Col. Sir H. A. Yorke from the post of Chief Inspecting Officer of Railways to the Board of Trade by superannuation, recalls an amusing incident in August, 1908, when Col. Yorke inspected a section of tramway track at Ealing, the condition of which had been complained of, by walking along it in company with representatives of the local authority, and was so far from being superannuated that he outdistanced the surveyor and the mayor, and covered 2 miles 10 yards in 27 minutes.

It is understood that the proposal of the National Electric Construction Company to deal with the Oxford tramway question by the installation of petrol-electric tramcars in the centre of the city and the overhead trolley system on the rest of the routes is recommended for acceptance by the Tramways Committee. Sir Alexander Kennedy has reported to the Council that the petrol-electric system is perfectly workable from the engineering point of view.

The opening of the Loetschberg Tunnel was postponed from the date originally announced, but last Saturday morning it was formally inaugurated by the passage of two special trains containing a number of visitors and officials. The trains, which were drawn by the single-phase locomotives which will be used for regular traffic, made the passage of the  $8\frac{1}{2}$  miles of tunnel in 14 minutes. The date for the commencement of ordinary traffic does not seem to have been settled as yet. It will be remembered that the construction of the tunnel was commenced in October, 1906, and the actual piercing was completed after considerable troubles had been overcome on March 31st, 1911. The total cost of the tunnel was about £4,000,000. Particulars of the electrical locomotives have already been given in ELECTRICAL ENGINEERING.

The Birmingham Tramways Committee have prepared a scheme of extensions which it is estimated will involve an expenditure of £245,709.

TELEPHONY AND TELEGRAPHY  
(INCLUDING WIRELESS)

On Tuesday, in the Appeal Court, contrary to expectations, the terms of the compromise between the Post Office and the National Telephone Company, by which both sides withdrew their appeals against the arbitrator's award, were not announced in Court. We are in a position to state, however, that as a result it will be possible for the National Telephone Company to pay off the deferred shares in full, and that there will be a handsome surplus, which will be dealt with subsequently as the Court may direct. One of the terms of the compromise is that the Government will liquidate the Exchequer bonds at 97 per cent. In the Company's Liquidator's report, recently issued, it was stated that, subject to the Company being successful in the appeal, there would be an estimated surplus of £137,470 after paying off the deferred shares in full, and after allowing for the 5 per cent. premium already paid in paying off the preferred shares. We understand that the surplus will now actually exceed this figure, although the appeals have been withdrawn, and the deferred shareholders who have already received 15s. in the £ will shortly receive the remaining 5s.

According to *The Times* correspondent at Copenhagen, a company has been formed to establish a wireless service on the Poulsen system from Denmark, via Greenland and Canada, to the Danish West Indies. The service is expected to be in operation by May next year.

The Postmaster-General was asked the question in the House of Commons last week whether in consideration of an expression of regret by Mr. J. E. Taylor, who was reduced in rank for investing in Marconi shares, the question of reinstating him in his former position would be considered. Mr. Samuel replied to the effect that he could not see his way to adopt this suggestion.

The Greek Government state that the islands of Choi and Metelin are now connected by a submarine cable.—Montenegro states that the office which that Government established at Skutari is now closed.—The Martinique-Paramaribo cable was once again repaired on June 27th.—A submarine cable has also been laid by the Greek Government connecting the Island of Imbros to the Island of Lemnos.

## LOCAL NOTES

**Aberdeen: City Electrical Engineer's Libel Action.**—The libel action in which Mr. J. A. Bell, the City Electrical Engineer, claimed £1,000 damages for slander against Mr. A. E. Milne, Hon. Secretary of the Aberdeen Branch of the Electrical Contractors' Association, ended last week in a verdict for Mr. Bell for £250 damages and costs. The action arose through Mr. Bell's advice upon an estimate by a local firm for an electric lighting and heating installation. From the papers in the case it seems that the estimate was for 23s. 1d. per point, and Mr. Bell, in the capacity of consulting engineer, expressed the opinion that this charge was excessive. Following on this, a letter was sent by the Hon. Secretary of the Aberdeen Branch of the Electrical Contractors' Association to the Aberdeen Town Clerk, commenting on this matter, and couched in language which Mr. Bell maintained was a reflection upon his ability, and implied ignorance, incompetence, and want of professional skill on his part. Further, he claimed that the letter was intended to damage him in the eyes of the Aberdeen Town Council, and that in fact he had been greatly injured in his professional reputation by the statements made, of which, by the way, a withdrawal of and apology for was refused. For the defendant it was claimed that the statements were privileged and that the letter in question was written under the instructions of the Association. Further, it was contended that, looking to the character of the work, the statements made by Mr. Bell were untrue. The judge, in his summing-up, held that the defendant was not privileged, and expressed the opinion that Mr. Bell, in making his comments upon the price quoted by the contractor, was not actuated by malice, as he did not himself carry out wiring work. The jury found that Mr. Bell had been accused of professional incompetence, and that the defendant had made statements reflecting upon his honesty which were untrue.

**Brighton: Electricity Accounts.**—In spite of the advice of the Electricity Committee and Mr. J. Christie, the Borough Electrical Engineer, that the sum of £1,406 profit upon the electricity undertaking for the last year should be transferred to reserve, as notified in our issue of June 19th, page 669, the Corporation has decided to transfer it to relief of rates. The Finance Committee of the Corporation took the somewhat unusual course at the beginning of the year of estimating, for the purpose of its annual forecast, a larger profit from the electricity undertaking than Mr. Christie anticipated would be the case, and, furthermore, the Finance Committee budgeted in advanced for this profit to be transferred to relief of rates.

**Colne: Heating and Cooking.**—The Council has decided to charge as from July 1st, one penny per unit for all current supplied for heating and cooking purposes where supply is at present taken for lighting.

**Cromer: Sale of Electricity Undertaking.**—The Board of Trade have decided to hold a local inquiry concerning the proposal of the Corporation to sell their electricity undertaking to Edmundsons' Electricity Corporation. This decision is the result of the very considerable local opposition to the proposal.

**Grimby: Engineer's Salary.**—By ten votes to six the Corporation has agreed to pay the Engineer a commission of 5 per cent. on the profits of the electricity undertaking when they exceed £2,500 per annum, the maximum amount on which this commission is to be paid being £4,000.

**Hove: Purchase of Electrical Undertaking.**—The Bill of the Hove Corporation to purchase the undertaking of the Hove Electric Lighting Co., Ltd., was before the Local Legislation Committee of the House of Commons last week, when some discussion took place as to the period for the repayment of the loan. The Corporation asked for thirty years, but the Local Government Board objected to anything beyond twenty years. The argument in favour of the longer period was that it is hoped to immediately reduce the price of current by  $\frac{1}{2}$ d. per unit, but if only twenty years were granted this could not be done. Eventually the Committee sanctioned thirty years in which the purchase-money should be repaid.

**Keighley: Electric Lighting Tariff.**—The lighting tariff has been amended so that consumers who take over 4,000 units per half-year will be charged 2 $\frac{1}{2}$ d. per unit.

**L.C.C.: Greenwich Power Plant.**—The Highways Committee of the L.C.C. report that none of the tenders received

for the purchase and removal of the Musgrave engines and other plant, which will not be required when the new turbines are installed, are satisfactory, and arrangements are being made for tenders to be invited in a slightly different form.

**Weston-super-Mare:** "Stealing" Electricity.—The proprietor of a "flying machine" on the old pier has been summoned for fraud in connection with the supply of electricity given by the Weston-super-Mare Electric Supply Co. It appears that the defendant has both a power and lighting meter, and it was discovered a short time ago that although his arc and incandescent lamps were burning, the lighting meter was not recording. On the other hand, the power meter was registering although the "flying machine" was not working. The Company resorted to the expedient of switching off the lighting current, which, of course, had no effect upon the lights, and followed this up by switching off the power supply, which immediately stopped the "flying machine" and also put out the lights. It was then found that he had connected his lamps to the power circuit with a view to getting the supply at 2d. per unit cheaper than the ordinary lighting rate. The further hearing of the case has been adjourned.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

### Generating Stations, Sub-Stations, Mains, &c.

**Belfast.**—A 3,500-ampere traction switchboard panel is required. (See an advertisement on another page.)

**Birmingham.**—Two 5,000-kw. turbo-generators are to be installed at the Summer Lane power station. Two additional cooling towers are also to be installed at an estimated cost of £6,300.

**Hebden Bridge.**—A loan of £3,250 has been sanctioned for additional plant at the electricity works.

**Ireland.**—A complete generating plant is required by the Roscrea Bacon Factory, Ltd. Secretary. July 11th.

**Ipswich.**—The Council have sanctioned an additional expenditure of £33,500 upon the electrical undertaking. About half of this sum is required for mains and services extensions, whilst the remainder is in connection with developing a new area to the east of Ipswich.

**Keighley.**—A loan of £6,800 has been sanctioned for electrical extensions.

**Leeds.**—Additional mains estimated to cost £10,200 are to be laid.

**London: Hackney.**—Sub-station plant and switchgear, conduits, and cranes are required by the Council. Borough Electrical Engineer, July 24th.

**Mile End.**—The Guardians of the Mile End Old Town require an electric lighting installation at their workhouse in Baucroft Road. Particulars from Clerk, Guardians' Offices.

**Stepney.**—The Finance Committee of the L.C.C. has sanctioned a loan of £25,000 in connection with the electricity undertaking.

**Sunderland.**—A standby motor-generator is required in connection with the tramway supply at an estimated cost of £2,000.

**Willesden.**—New sub-station at Acton Lane. Borough Electrical Engineer.

### Wiring

*The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.*

**Barrow-in-Furness.**—New theatre.

**Birmingham.**—Alterations and additions to Maxstoke Schools. Architects, Buckland & Farmer, Norwich Union Chambers, Congreve Street.

**Coventry.** Municipal Technical Institute.

**FOR  
STEAM JOINTS  
USE**

**JOHN HUDSON & CO.'S SUCCESSORS, Mansell St., London, E.**

**Darlington.**—Harrogate Club and Institute. Architect, G. W. Davis, High Road Chambers.

**Dublin.**—New art gallery.

**Finchley.**—200 working-men's houses. Clerk to Council.

**Greenock.**—Electric lighting at Ladyburn School. Architect, A. C. Thomson, Ayr.

**Lancaster.**—New mill. By Lord Ashton.

**Manchester.**—Public baths and wash-houses. New Quay Street.

**Portsmouth.**—Electric lighting installation in boys' secondary school, Victoria Road, N. Town Clerk, July 8th.

**Scarborough.**—Three hundred and sixty-light installation at the workhouse and infirmary. Clerk to Guardians, 14 Dean Road.

**Twickenham.**—Considerable additions to Orleans Council School.

**Wallasey.**—The Local Government Board has sanctioned a loan for a new town hall.

**West Ham.**—Electric lighting installations at Forest House workhouse and Forest House cottages, Leytonstone. Clerk, Union Road, Leytonstone.

### Miscellaneous

**Llandiloos.**—Street lighting for a period of seven years. (See an advertisement on another page.)

**London: L.C.C.**—A supply of incandescent electric lamps is required, at an estimated cost of about £200.

**H.M. Office of Works.**—Twelve months' supply of electric cable and wire. Storekeeper, 12 Lambeth Palace Road. July 11th. (See advertisement on another page.)

**St. Pancras.**—The Council has decided to replace the arc lamps in Tottenham Court Road by lamps of more modern type.

## TENDERS RECEIVED AND ACCEPTED

**Admiralty.**—An order has been placed with Messrs. S. Blaikie & Son, of Kirkwall, for the erection of a wireless telegraph station at Brough Head, Orkney.

**Bedworth.**—Tenders have been received by the Council for the lighting of the streets by electricity and gas, and the tender by the Leicestershire & Warwickshire Supply Company, at £3 10s. per 50-candle-power lamp per annum, including maintenance and repairs, has been accepted. The gas company's tender was £3 15s. per annum for a minimum of 100 lamps, the Council providing the standards and keeping the lamps in repair. In the gas company's tender the candle-power of the lamps was from 75 to 85.

**Belfast.**—The tender of Messrs. Dick Kerr & Co. has been accepted for tramway track renewals.

**Bolton.**—The tender of Messrs. Musgrave & Co. has been accepted for condensing plant.

**London: L.C.C.**—The following tenders have been received for a supply of high and low tension cables:—Western Electric Co., Ltd., £25,409 16s.; Johnson & Phillips, Ltd., £26,018 3s.; Siemens Bros. & Co., Ltd., £26,169; W. T. Henley's Telegraph Works Co., Ltd., £26,187 10s.; Callander's Cable & Construction Co., Ltd., £26,941 18s.; W. T. Glover & Co., Ltd., £27,201 5s.; British Insulated & Helsby Cables, Ltd., £27,837 11s. The lowest tender, namely, that of the Western Electric Co., Ltd., is recommended for acceptance.

**Stalybridge.**—The following tenders have been accepted by the Joint Tramways and Electricity Board:—Economisers, Goodbrand & Co.; feed-water filter, Babcock & Wilcox.

**L.C.C. Armature Winders.**—The armature winders in the employ of the L.C.C. Tramways Department recently asked for an advance of wages from 9½d. to 10½d. an hour. The matter was referred to the Conciliation Board, and an agreement has been arrived at on the basis of the rate of pay being increased to 10d. per hour.

**An Osram Fire Brigade.**—In every department of the organisation of the General Electric Co. the importance of an efficient fire brigade is fully recognised, and a new brigade has recently been formed at the central stores in Union Street, Southwark, which are worked in conjunction with the Union Street works, and where the main stock of Osram drawn wire lamps is stored. The brigade consists of 23 members, with Mr. C. Rennie as captain. Mr. W. Riley, formerly of the Metropolitan Fire Brigade, has been engaged as instructor, and weekly drills are being held. Practice has shown that the staff can be dismissed from the premises and the firemen be at their posts in 30 seconds.

## APPOINTMENTS AND PERSONAL NOTES

Lt.-Col. P. G. von Donop has been appointed to succeed Lt.-Col. Sir H. A. Yorke as Chief Inspecting Officer of Railways to the Board of Trade.

Mr. J. W. Beauchamp, Chief Electrical Engineer to the West Ham Corporation, has been elected a member of the "Point Fives."

The salary of Mr. T. R. Whitehead, Manager and Engineer of the Coventry Corporation Tramways, has been increased from £400 to £450 per annum.

Mr. H. E. Blain, who, as we recently announced, has resigned his position as General Manager of the West Ham Corporation Tramways, has been appointed Assistant Purchasing Agent to the District & Associated Tube Railways.

Mr. William Travis has resigned his position as Chief Assistant Engineer to the Hastings Corporation Electricity Department, and has joined the staff of the Brompton & Kensington Accessories Co., Ltd.

Mr. Frank Bailey has been awarded a silver medal by the Royal Society of Arts for his Paper on "Electric Supply in London," and Dr. F. Mollwo Perkin has a similar award for his Paper on "Natural and Synthetic Rubber."

Competent electrician, wanted for 3-phase coal-cutters during night shift. (See an advertisement on another page.)

An electrical engineer is required for the United Provinces of Agra and Oudh. Application to the Director-General of Stores, India Office, Whitehall.

A Junior Switchboard Attendant is required at Derby. (See an advertisement on another page.)

A Shift Engineer is required at Ipswich. (See an advertisement on another page.)

Switchboard attendant; also driver, required in the Stoke-on-Trent Electricity Department. (See an advertisement on another page.)

## MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. G. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night was £67 10s. to £80 (last week £67 15s. to £68 5s.).

**Peebles' Annual Outing.**—The employees of Messrs. Bruce Peebles & Co. went for their annual excursion on Saturday last. St. Andrews was the place selected, and the whole outing proved a thorough success.

## COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

**Crompton & Co.**—With reference to the scheme for the rearrangement of capital referred to in our last issue, we are informed that this has been successfully carried through and the new shares allotted. The new Company takes over all the assets and pays all the liabilities of the old Company. The new board has been strengthened by the addition of Mr. A. A. Campbell Swinton and Mr. W. Churchill Hale. Mr. Thomas Britten, for many years with the Electric Construction Co., has been appointed Works Manager in succession to Mr. A. J. Hodgson, who resigned in November last, but continued his duties at the request of the board until the new scheme had been carried through. Mr. E. Reeves, Joint Manager of the old Company, now becomes Managing Director.

**R. Waygood & Co.**—At the Annual Meeting last week a final dividend, making 7 per cent. for the year was declared, and the sum of £9,691 was carried forward. The Chairman stated that the Company has secured the contract for 32 lifts for the new hotel in Regent Street now being built by the Strand Palace Hotel Company. Additional capital is to be raised in order to meet the rapid development of the business.

**Meter Approved.**—The Board of Trade has approved of the Electrical Company's polyphase meter type Da., and for the means provided for fixing same.

## ARON ELECTRICITY METER

THE annual meeting was held at Winchester House on Tuesday this week, Mr. H. Hirst, Chairman of the Company, presiding. After the notice convening the meeting had been read, the Chairman said:—

It is my pleasure to move that the report and accounts as submitted to the shareholders be taken as read. You will no doubt share the satisfaction which your Board feel at the continued progress of our Company. The year under review has not been one of continual sunshine; many a black cloud has appeared in one or other of the territories in which we operate. The rise in the price of raw material, political troubles, and labour unrest have all contributed to the anxiety of your Board and management. Nevertheless, the result of the year's work is exceedingly pleasing, and our net profit of £32,652 is about £2,000 ahead of last year. This practically represents the exact amount of the increase in our gross profits, which are £53,000. That is proof that the same careful principles have prevailed during the last year which have helped us in the past in lifting this Company from adverse conditions into a flourishing concern with every appearance of continued progress. So much for the profit and loss. As regards the balance sheet, the items are clear, and I cannot think of any necessary comments except so far as the first item on the credit side is concerned, viz., £213,298. This item, I notice, from correspondence and inquiries which I have received, is looked upon by many shareholders as representing goodwill and patents only. The people who complain most about the insufficiency of details in balance sheets are generally the greatest sinners in the way of reading them. This item includes such solid assets as valuable freehold land in Schwerdnitz, Vienna, and Pau, very important and expensive buildings, modern machinery, and tools. The actual hard cash spent on additions to these items since the formation of the Company amounts to a grand total of £120,000. I personally am of opinion that the actual amount for goodwill and patents has been, by very generous depreciation on the one side and by reserves on the other, reduced to quite a normal and unimportant figure. I doubt very much, if our property were valued to-day by a conservative valuer, whether he could debit that account with more than £50,000 for goodwill and patents. Perhaps the Board, for the satisfaction of the shareholders, will arrange in the coming year for such a valuation to be made. The only other comment of utility which I can make is with reference to the appropriation of our profits. The Directors have decided to recommend the payment of a dividend on the ordinary shares of 7 per cent., or 1 per cent. more than last year. No doubt there are those among you who think we ought to pay more. I wish to assure you that the Directors have given the fullest consideration to this problem. The constant increase of business absorbs our finances to the full, and I may tell you that during the period which has elapsed since March 31st this year, to which date our accounts are made up, our sales have again gone up considerably as compared with the same period of last year. Whilst business increases, the profits do not show entirely in cash, but largely in the additional outstandings of stock necessary to satisfy our customers. In addition to this it must not be forgotten that the bulk of the business of this Company is done in the central European countries—Germany, Austria, France, and Belgium. The war cloud which hung over Austria has not entirely disappeared, and whilst we have no fear of severe bad debts, we have to deal with slower payments and increased outstandings. The present financial position in other countries is so well known that I am sure if you give the situation one moment's thought you will agree with us that this is not the time when we should part too lightly with such liquid assets as hard cash. The whole of the future welfare of this Company might be seriously affected by so doing. I wish again to thank Professor Aron and his staff for the skilful manner in which they have handled our business during the past year. I now formally move that the report and accounts as audited and submitted to the meeting be received and adopted.

Sir James Pender seconded, and after the Chairman had answered one or two questions put by shareholders, the Report and Accounts were carried unanimously.

The Chairman then proposed that the dividends of 3 per cent. on the preference shares for the six months to March 31st, 1913, and of 7 per cent. on the ordinary shares for twelve months to the same date, as recommended by the directors, be paid. Mr. Roger W. Wallace, K.C., seconded.

Mr. Roger Wallace, K.C., then proposed the re-election to the Board of Mr. H. Hirst and Sir James Pender, which was seconded by Colonel Crompton, and the proposal was carried.

Mr. Fisher then proposed the re-election of the auditors, Messrs. Price, Waterhouse & Co., which was seconded by Mr. Ashby and carried.

The auditors were unanimously re-elected.

A vote of thanks to the Chairman, proposed by Mr. Edgar Newgass, and seconded by Mr. A. G. Sawell, closed the proceedings.

## SUMMARY

THE petition for an extension of term of the fundamental telegraph patent beyond the customary 14 years was heard by Mr. Justice Warrington on Tuesday and Wednesday. The extension was, however, not granted. (Page 404.)

THE conclusion of the Paper read recently by Mr. B. Welbourn and the discussion thereon is reported this week. (Page 405.)

AN example of indirect lighting is illustrated on page 406.

AN instrument for magnetising permanent magnets is described. (Page 407.)

PARTICULARS are given of a large cable in use on board ship. (Page 407.)

SOME street lighting fittings are illustrated on page 408.

THE calculation of the mechanical forces on transformer coils on short circuit is discussed in our Questions and Answers columns. (Page 409.)

A PATENT for electric automobiles, in which each wheel is driven by a special design of motor, by E. Cantono, expires this week after a full life. The specifications published last Thursday include one for a method of joining tungsten to copper by the B.T.H. Co., one to enable "inching" to be easily carried out

with automatic motor starters by F. Broadbent, and one for a universal method of obtaining sparkless commutation in dynamo and motors by M. Déri. (Page 410.)

AN agreement is said to have been arrived at between the Metropolitan and Great Northern Railway Companies for the working of the Great Northern and City tube railway. (Page 411.)

A NEW contract for the Imperial wireless telegraph scheme is being negotiated with the Marconi Company.—£10,000,000 is to be spent on telephone developments.—Dissatisfaction has been caused by the imposition of a fee of one guinea by the Post Office for experimental wireless telegraph licences. (Page 411.)

SUBSTANTIAL profits were made last year by a number of large provincial electric supply undertakings.—A new regulation with regard to electric cooking apparatus has been framed by the Board of Trade.—Supply at Newcastle-under-Lyme has been changed over to the three-wire continuous-current system. (Page 413.)

EXPENDITURE on new plant is contemplated as follows:—Sheffield, £130,860; Cardiff, £30,000; Loughborough, £14,000; Peterborough, £7,000; Stoke-on-Trent, £1,555; Belfast, £35,000; Hamilton, £10,000; Manchester, £75,000; and South Shields, £30,000. A large quantity of cable is required in Australia, arc lamp carbons in Malta, and turbo-alternators at Shipley. (Page 413.)

A 10 per cent. dividend is recommended by the General Electric Co., and 5 per cent. by the Electric Construction Co. (Page 414.)

**Damage to Electricity Mains.**—The Charing Cross, West End, and City Electricity Supply Co. have been successful in an action against the London Hydraulic Power Co. for damage to their electric mains, due to burst water mains. Mr. Justice Scrutton found that the Hydraulic Power Co. was liable for damages, notwithstanding that he did not find the company guilty of negligence, on the ground that their statutory powers are qualified by the proviso that they would be liable at law for any nuisance caused by their works.

**Load Factors of Large Power Stations.**—With the increasing diversity of the load on large power stations, and the better terms offered for limited night and early morning supply, the load factors are steadily improving. The following figures for December, 1912, are of interest. The Commonwealth Edison Co. of Chicago had a peak load of 233,000 kw., an annual output of 799 million units, and a load factor of between 43 and 44 per cent. The New York Edison Co. had a peak load of 210,800 kw., an annual output of 619 million units, and a load factor of 33·4 per cent. The Brooklyn Edison, Boston Edison, and Philadelphia Electric Companies, with peak loads of from 40,000 kw. to 66,000 kw., had load factors of 33·7, 30·6, and 32 per cent. respectively. The Victoria Falls and Transvaal Power Co. expect the load factors of most of their stations will shortly be in the neighbourhood of 70 per cent., on account of the almost continuous work at the mines.

### THE "TELEGRAPHONE" PATENT

THE oft-delayed petition for extension of term of the fundamental patent (No. 8,961, of April 28th, 1899) for the "telegraphone," by the Telegraphone Corporation (of New York), was considered by Mr. Justice Warrington in the Chancery Division on Tuesday and Wednesday last. The patent was granted to V. Poulsen (Denmark), and covers the storage and reproduction of spoken words, &c., by a moving wire or band electro-magnetically (ELECTRICAL ENGINEERING, Oct. 31st, 1912, p. 600). After hearing the evidence in support of an extension, the judge decided that the petition had failed, largely because little attempt had been made to manufacture in this country, and because the patentee was only indirectly interested in the petitioning company.

There was no opposition, and the Board of Trade, through the Solicitor-General, stated that, in order to obtain the special privilege of extension, petitioners must prove that the invention is of great public utility, and as so few machines had been sold it would seem that they were not of much utility. It was also necessary to show that great efforts had been made to establish manufacture. He also said that the case of an assignee was not so strong as that of a patentee. The petition did not contain any indication that the patentee had made £10,000 by the sale of shares in one of the companies, as had transpired in evidence.

It appears that since 1899, the patentee, in conjunction with Professor Pedersen, of Copenhagen, has been continuously experimenting to improve the apparatus, until now by using steel piano wire on two drums driven by either one or two motors to rewind the wire from one drum to the other and pass it under the "talking" electromagnet, so that the latter is not worn away, a machine has just been produced which is said to be fool-proof and is capable of recording or reproducing messages for thirty minutes with a single wire, whereas the original machines could only run for about thirty seconds. In addition an indicator shows where one message ends and another begins, and the wires when filled can be changed in about five seconds. Mr. J. Swinburne, who gave evidence, saw a future for the telegraphone for tape machines, for machines like the "Dictaphone," and for teaching singing and foreign languages, &c., as the reproduction is very clear and not broken by extraneous sounds.

It appears that a company was formed in Denmark when the patent was taken out; this parent company sold the manufacturing business to subsidiary companies in different parts of the world including Denmark, Mexico, America, Canada, and Germany. None of these companies paid any dividends, and in Canada and Mexico the companies are in a moribund condition, while the German interests were handled by Siemens & Halske and subsequently by other companies, who have been unable to make any progress at all in that country. Since January the Telegraphone Corporation of New York, as the American Selling Co. (who take the machines from an American manufacturing company), sold several machines, but very few of the earlier types have been disposed of. The Telegraphone Corporation holds the patents, all of which are in force, for practically every country in the world except Mexico, Canada, Germany, and Denmark. The patentee and Professor Pedersen are still interested in the various companies, and seem to have received so far only £4,439 for the fundamental patent and the subsidiary patents relating to constructional details which have enabled the present perfected machines to be produced, besides the £10,000 by the sale of shares.

**Examination in Electric Light Switching.**—Messrs. A. P. Lundberg & Sons (479 to 487 Liverpool Road, N.) have for long given great attention to the development of convenient systems of control for electric lamps, and in addition to designing and manufacturing suitable apparatus for the purpose, have done much by the publication of literature and otherwise to spread a knowledge of this hitherto rather neglected subject. Their latest step in this direction takes the form of a scheme of examinations, which will be conducted for them by Mr. W. Perren Maycock. On the results of these not only will certificates be given, but a certain number of money prizes, from £3 downwards, will be awarded, and prizes consisting of copies of their book, "Small Switches and their Circuits." There are three grades of certificates: elementary, intermediate, and advanced; and the lighting engineer, engineering student, contractor, foreman, and wireman, will find that the examination paper is full of tests suited to their varying capabilities. All they have to do is to write for one to Messrs. A. P. Lundberg & Sons, and then send in their answers by the time specified therein. The first series of results will be announced in November. We should add that there is no entrance fee of any kind.

### MORE WHITWASH.

The POSTMASTER-GENERAL, replying to a Deputation from the London Chamber of Commerce last Friday, said that many of the complaints with regard to the inefficiency of the telephone service were untrue and many were couched in the most exaggerated terms; but, nevertheless, he proposed to spend £10,000,000 on the development of the service during the next few years.

## ALUMINIUM v. COPPER CABLES

IN our last issue we published the first part of a Paper on aluminium and copper cables, by Mr. B. Welbourn, read before the Institution of Mining Engineers. The latter parts of the Paper dealt with overhead cables and jointing.

Usually, said Mr. Welbourn, overhead cables are considerably cheaper than insulated cables, and the saving that may be effected frequently is as much as 50 per cent. The procedure to be followed before any overhead line may be erected in the United Kingdom is rather tedious, except where the line is entirely erected on private property. The governing authority is the Board of Trade, who will, on application, furnish copies of their regulations, and of the "Model Description." Before commencing the work, it is necessary to send for approval a description of the proposed line to the Board of Trade. It must not be assumed from reading this "Model Description" or the regulations that no variation is permitted in regard to factors of safety. The attitude of the Board of Trade's electrical adviser regarding factors of safety and other details is very reasonable, and usually the best way to solve any difficulty is to have an interview with him. It is customary to use a stranded conductor, because its breaking-strain is greater than for a solid conductor of equal cross-sectional area. It is also usual to employ the smallest practicable number of wires in a strand, so that each wire may be made to take its proper share of the longitudinal stress; but it is not advisable to use any aluminium wire exceeding 0.25 inch in diameter; and in conductors up to 0.25 sq. in. no individual wire should exceed 0.169 inch in diameter.

There are legitimate differences of opinion as to factors of safety for copper and aluminium wires. The practice varies widely: for example, in North America, where both aluminium and copper overhead lines are extensively used, the maximum stress employed for both copper and aluminium is 250 per cent. greater than is called for in the British Board of Trade regulations. Making allowance for the elasticity of the metals, experience shows that in most parts of the United Kingdom it is sufficient to allow 17 pounds per sq. ft. of wind pressure and a factor of safety of  $3\frac{1}{2}$  for copper and  $4\frac{1}{2}$  for aluminium at a temperature of  $22^{\circ}$  F. when metals are employed which are of the quality previously suggested in this paper.

Mr. Welbourn gave the following comparisons of costs in actual cases which have occurred:—

(1) In 1910 Messrs. Kennedy and Jenkin, as consulting engineers to H.M. Secretary of State for War, issued specifications for 7.6 miles of 3,000-volt, four-wire, three-phase lines at Aldershot. The strength of poles, length of span (200 feet), &c., were kept the same throughout for the conductors, which were of 0.10, 0.05, and 0.025 sq. in., respectively, for aluminium, or equivalent copper. The tendered prices showed a saving of 7.42 per cent. in favour of aluminium, with copper at £60 5s. and aluminium at £74 10s. per ton.

(2) In 1910, under the scheme prepared by Mr. M. H. Habershon, two 600-volt, two-wire, direct-current lines were erected for Messrs. Newton Chambers and Company, Ltd., at Rockingham, Yorkshire, as follows:—(a) A 950-yard run of two 0.40 sq. in. (19/0.164 in.) double-braided aluminium conductors to carry 150 kw. (b) A 2,100-yard run of two 1.40 sq. in. (37/0.222 in.) bare aluminium conductors to carry 500 kw. 40-yard spans were allowed for aluminium and 50-yard spans for the equivalent copper cable. Line (a) erected complete, including all poles, was 25 per cent. cheaper in aluminium than in copper. Line (b) erected complete, including all poles, was 27½ per cent. cheaper in aluminium than in copper.

(3) In 1912, a 6,600-volt three-phase line was built for the Ebbw Vale Street Coal and Iron Company, Ltd., for whom Messrs. Walter Dixon and Company, of Glasgow, act as consulting engineers. The 5,850-yd. run of line, using 7/0.196-in. bare aluminium wires, and capable of carrying 1,100 kw. without any overloading, showed a saving in favour of aluminium of 20 per cent.

Experience has shown in North America that there is much less trouble with aluminium than with copper from ice and snow collecting on the conductors; and if in the future it can be demonstrated that aluminium does not collect these as readily as copper does in this country, then modifications in pole design, &c., will follow, with a further saving in cost in favour of aluminium. Aluminium conductors, being very light and of larger diameter than copper, are blown up vertically as well as horizontally in strong gusts of wind, and they require to be amply spaced, which increases the cost. So far as the author knows, copper wires in this country are never blown in any other direction than sideways.

Dealing next with jointing, the author said that so far as his experience goes, there is not a single solder which is permanently satisfactory, and he does not recommend either cast-aluminium joints or autogenous welding for cables, owing to the effect of the heat on the insulation. On the other hand, he confidently recommends the type of joint used on the large aluminium cables in Manchester, described in *ELECTRICAL ENGINEERING* of Nov. 24, 1910.

Usually, in this country joints on copper and aluminium conductors on overhead lines are made at an insulator, so as not to be under stress. Copper joints can be easily made in various ways. Probably the best method on overhead lines, or on insulated cables carrying any considerable current, is by means of flexible copper braid bound and soldered to the joint, a method by Mr. Chas. Vernier, for use on both overhead and underground conductors.

There are various ways of jointing aluminium conductors on overhead lines. Up to 0.25 sq. in. welded joints can be made by making the ends butt inside a metal sleeve and heating them by means of a blow-lamp until the ends can be forced together by hand. After cooling, the metal sleeve is then removed. This type of joint must not be subjected to stress. It was used throughout on the Aldershot lines already mentioned, with the approval of Messrs. Kennedy and Jenkin, and has proved entirely satisfactory, its conductivity being higher per unit length than that of the hard-drawn conductors themselves. It is also being used for some of the lines under construction for the War Office on Salisbury Plain.

Another way of jointing large conductors is by means of the type of clamp-joint similar to those described in the articles on aluminium cables already referred to, but without the cast-iron protecting box. Such a joint cannot be used under stress, and it should be painted, immediately after fixing, with a high-class paint, in order to prevent oxidation of the strands inside the clamp.

The well-known torsion sleeve-joint may be employed for jointing conductors up to about 0.30 sq. in., under strain. It has not been much used in this country, but it is commonly employed in the United States and Canada, and is understood to be satisfactory. It should also be painted.

A specially-designed joint for use under stress was employed on Messrs. Newton Chambers & Co.'s 1.4 sq. in. line. It is clearly shown in Fig. 1, and has been quite

FIG. 1.

successful. To prevent electrolytic action, the steel holding-bolts were stoved and enamelled. It should be painted as mentioned above.

## DISCUSSION.

Mr. Robert NELSON (H. M. Chief Electrical Inspector of Mines) felt generally in the position of being able to agree with Mr. Welbourn on the Paper, and one point he would emphasise was the preference expressed for lead-covered cables. It was quite correct to say that, as an electrical apparatus, there was nothing more reliable than the lead-sheathed and armoured cable, and for a mine where there might be some slight risk of accident there was no safer method of transmitting electrical power.

Mr. A. RICHARDS (W. T. Glover and Co.) regretted that Mr. Welbourn had not entered into a more detailed discussion of paper v. bitumen. He agreed that too much stress was often placed on the corrosive action of water. Very often water was reputed to be bad for cables when it was not so. He had had a case quite recently in which he was told that a certain pit water was strongly alkaline, but it turned out to be slightly

acid. In his opinion vulcanised bitumen cable had advantages over lead-sheathed: it was much more flexible, and for awkward places this gave it a great pull over the lead-covered cable; the jointing was simpler, and the terminals could be treated in a much more haphazard way. He mentioned a curious instance of what a bitumen cable would stand. It had been on its drum for five years, not having been delivered owing to some dispute, but although the drum was found to be rotten, the cable itself was as good as when made. It was decided to instal it in a pit, and in doing so, through an accident, the whole thing went down the shaft and had to be hacked to pieces. They took seven of the worst pieces and tested them, and six out of the seven stood the full working pressure of 3,300 volts, whilst the other one took 10,000 volts. Another similar instance was that of a low-tension cable which was accidentally dropped down the shaft, and was got out again in two or three lengths and put to work. He could not imagine a paper, lead-covered cable standing this. He did not agree that Mr. Welbourn's joint was quite as simple as he tried to make out, and he criticised the figures given for the resistance of the Manchester aluminium cable joints. Mr. C. J. Beaver, he said, had made many tests of conductivity of joints of that description, and the best he got was 66 per cent., and of the torsion joint used in America, some were as bad as 6 per cent., and none better than 60 per cent. The difficulty of torsion joints appeared to be in the contact. It seemed to be necessary to get hold of each individual wire in order to get good contact.

Mr. A. Jacob (British Aluminium Company) said that aluminium showed to the best advantage on insulated cables in connection with low-tension feeders where the cross-section of the conductor was relatively large. He was pleased to note Mr. Welbourn's conclusions that, at the average price of aluminium and copper—the price of aluminium being abnormally high at present—there was real economy in using aluminium in connection with that particular class of cable. He agreed with Mr. Welbourn on the question of welding, and as there were at least 15,000 tons of aluminium transmission lines in operation, it was clear that these joints had been effective. There was a good deal in the making of the joint. In the making of the torsion sleeve joint it was desirable to have the sleeve as close a fit as possible to the conductor, and not make the twists too short. The reason for the present high price of aluminium was entirely due to the increasing use of the material, which had absorbed all the available stocks. There was considerable shortage of the metal at the moment, and producers were busy increasing their output as fast as they could get concessions for the necessary water power, which was the key to the economic production of aluminium; the present condition as to price was only of a temporary character. As a matter of fact, the development of the electrical uses of aluminium had been so rapid that it would take manufacturers all their time to keep pace with this demand alone.

It was announced that the Paper should be further discussed at the Annual Meeting of the Institution in Manchester in September.

**Electric Zinc Smelting in France.**—According to the Board of Trade Journal, an interesting development in the French electro-metallurgical industry is announced in the formation of a company for the production of zinc in the electric furnace by a process invented by two Frenchmen. A similar method is already being worked in Norway, but in France zinc ore has hitherto been treated in furnaces heated with coal, and owing to the heavy cost of the carriage of this fuel, smelting has been confined to coal-bearing districts, which are for the most part far from the deposits of zinc. The carriage of ore to the coal-fields, though less costly than the transport of coal to the zinc mines, throws a heavy burden on the industry, and necessitates preliminary treatment at the mines in order that the percentage of metal in the ore to be transported may be as high as possible. As a result of these conditions, the French zinc mines have hitherto been comparatively neglected; but the employment of water-power, which exists in abundance in close proximity to the zinc mines in the Pyrenees, will, it is believed, create a new situation. It is hoped that production will be rendered more economical by the use of the electric furnace instead of coal, while the cost of labour will be very considerably diminished owing to the simplicity of the electric process and the small number of hands needed to work it. Preliminary experiments have been carried out at Arudy (Basses-Pyrénées) and Ugines (Haute-Savoie), and the rights have been acquired by a company which has bought falls at Arrens (Haute-Pyrénées) capable of generating 7,000 h.p. Power will be conveyed to smelting works at Argeles, situated within easy distance of all the principal zinc deposits in the district (Pierrefitte, Chèze, Arrens, and Anglas). The works at Argeles will not be ready for two years, and the company, in order not to lose time, has meanwhile rented some existing works in Savoy having rights over water-power of 1,500 h.p., and conveniently situated for receiving ore for treatment. It is proposed to devote these works chiefly to the production of white zinc, for which there is a big demand in France now that the use of white lead is forbidden.

## INDIRECT LIGHTING AT RUGBY SCHOOL

ONE of the latest "eye-rest" installations which has been designed by the British Thomson-Houston Co. (Mazda House, Upper Thames Street, E.C.) is in the Temple speech room at Rugby school. This installation completely upsets all the charges of "shadowlessness" and "flatness" which have been urged against indirect lighting. The illumination is certainly uniform and well diffused, but there is no suppression of detail or relief. The room is fairly lofty and the "eye-rest" fittings are suspended close to the ceiling, but the pictures on the lower part of the wall are excellently lighted. The installation consists of one 55-inch fitting, con-

THE TEMPLE SPEECH ROOM, RUGBY.

taining nine 200-watt Mazda lamps in the centre of the room; one 36-inch fitting, containing nine 100-watt Mazda lamps at each end; and one 24-inch fitting, containing three 100-watt Mazda lamps in each of the transepts. There are thus five "eye-rest" fittings in all, containing Mazda lamps with a total wattage of 4,200. The fittings are attached to the ceiling by means of contact suspension gear, so that they can be lowered to the ground for cleaning.

## PAINT SPRAYERS

THE use of the ordinary brush for the distribution of paints, lacquers, varnishes, enamels, &c., over large areas is rapidly being superseded by the sprayer, which distributes the material quicker and much more evenly, giving work that is much more penetrative, while effecting great economy in material. A number of patterns of this are described in a list issued by the F. Crane Chemical Co. (Armoury Close, Bordesley Green, Birmingham), ranging in price from 45s. upwards, in capacities of a pint or quart. They embody a number of

good points in design and construction, which are the result of extensive experience. One pattern is illustrated here.

**Kelvin Memorial.**—On Tuesday next, at 3 p.m., the dedication will take place in Westminster Abbey of a window in memory of Lord Kelvin. The window, which is the result of action taken by engineers in the British Dominions and the United States, has been placed in the north aisle of the nave, in close proximity to the one erected in 1909 by civil engineers to the memory of Sir Benjamin Baker, and has been designed and made by the same artist, Mr. J. N. Comper. A special service is being arranged, and Mr. R. Elliott-Cooper, President of the Institution of Civil Engineers, will make the formal presentation of the window on behalf of the donors. Members of the American Engineering Societies and of the Canadian Society of Civil Engineers who may be in London at the time are invited to attend the dedication ceremony, whether they subscribed to the cost of the window or not, and they may obtain cards of admission by writing before Monday, July 14th, to the Secretary of the Institution of Civil Engineers, 12 Dartmouth Street, Westminster, S.W.

## MAGNETISING PERMANENT MAGNETS

A NEW magnetising device for permanent magnets has just been designed by the Witton Kramer Electric Tool and Hoist Co. (for whom the General Electric Co., Ltd., of 67 Queen Victoria Street, London, E.C., are the sole selling agents), which has been specially designed at the request of large manufacturers of permanent magnets with a view to enable a large magnetising force to be effectively applied to the magnet during the magnetising process. As will be seen from the accompanying illustration, it consists of a strong electro magnet with steel pole-pieces working along slides, machined and fitted with high accuracy. The moving poles may be drawn together by a right and left-handed copper screw. The permanent magnet is gripped between the two pole-pieces by operating the hand-wheel attached to the screw. The particular magnet shown requires 1 kw. to energise it. The jaws may be opened out from 1 in. to 8 in. The exact procedure that has to be followed during the magnetising process has to be chosen with very great care. No advantage is to be gained by retaining the magnet in the jaws for a long period, since the resulting magnetism depends not upon the time, but upon the maximum magnetising force applied. Hence the importance of a strong magnetising force with a

MAGNETISING APPARATUS FOR PERMANENT MAGNETS.

low reluctance in the path of the flux. An advantage is to be gained for magnets that need to have extreme constancy, through slightly reducing the magnetism several times by subjecting them to demagnetising forces during the treatment. The best procedure to follow is, after putting the magnet in the jaws, switch on the current to its full value. Then the current is reversed, and the magnetising force applied in the opposite direction. This is repeated several times, and on the final application of the current in the correct direction for magnetising the current should not be suddenly switched off, but should be diminished gradually to zero, otherwise the inductive kick of the coil would exert a demagnetising influence. A number of these magnetising devices have been supplied to various firms for making permanent magnets for meters.

**The Batti Wallahs' Journal.**—The third issue of the bright quarterly official journal of the Batti Wallahs Society contains some amusing and interesting items, including the semi submarine experiences of some members who participated in an eventful down river trip in a motor launch.

**Osram Lamps in China.**—The General Electric Co., Ltd. (67 Queen Victoria Street, E.C.), have sent us illustrations of several buildings in China now lighted by Osram lamps, including a Shanghai club and a hotel, and some street scenes where they are used.

**Electric Heating.**—Dr. Niethammer reports in *Elektrische Kraftbetriebe u. Bahnen* that the New York Edison Co. have now over 3,000 kw. connected in heating and cooking apparatus. In some tailoring establishments a consumption of 350 units per flat-iron per annum is reached. For private houses the 6 lb. flat-iron is most favoured, the average time in use being 14 hours per month, and the average consumption 84 units per annum.

## A LARGE CABLE ON BOARD SHIP

AN interesting item of information has been sent us regarding the new battle cruiser *Australia*, which will be the flagship of the first unit of the Australasian squadron, by W. T. Henley's Telegraph Works Co., Ltd. (Blomfield Street, London Wall, E.C.). This vessel is fitted as part of her electrical installation with a ring main cable, which is, we believe, the largest that has ever been installed on any ship. We reproduce a full-sized section of this cable in the

SECTION OF RING MAIN CABLE ON H.M.S. "AUSTRALIA."

figure. It will be observed that its diameter is nearly 3 in. The sectional area is 2 sq. in., and its weight per thousand yards 23½ tons, the specification being as follows:—169 H.C. tinued copper wires, each 0.124 in diameter, insulated with long fibre paper sheathed with a solid drawn tube of lead, served with tarred jute yarn and armoured with galvanised steel wires, left bright. H.M.A.S. *Australia* was built by Messrs. John Brown & Co., Ltd., of Clydebank, and the cable referred to above, as well as the whole of the cable used in the vessel, was supplied by Messrs Henley's.

**The International Electrical Congress at San Francisco in 1915.**—Arrangements are advancing for the International Electrical Congress which is to be held in San Francisco during the week beginning September 13th, 1915, in conjunction with the Panama-Pacific International Exposition, under the auspices of the American Institute of Electrical Engineers. The Congress is being divided into twelve sections relating to: *Generation, Transmission, and Distribution*.—Central station and sub-station design, control and operation. Long-distance transmission of electric power. *Apparatus Design*.—Generators, motors and transformers. Prime movers and their relations. The rating of machinery. *Electric Traction and Transportation*.—City, surface, and rapid transit railways; inter-urban and trunk lines; electric vehicles, ship propulsion, mining railways, elevators and hoists. *Electric Power for Industrial and Domestic Use*.—Factories, mills, refrigeration, heating devices, &c. *Lighting and Illumination*.—Arc and incandescent lighting; the science and art of illumination. *Protective Devices*; *Transients*.—Switches, circuit-breakers; condensers; electrostatics; disruptive phenomena; high frequency phenomena. *Electrochemistry and Electrometallurgy*.—Electrolytic and metallurgical apparatus and processes. *Telegraphy and Telephony*.—(a) All communication of intelligence by the use of wires; (b) Electromagnetic waves and radio-telegraphy and telephony. *Electrical Instruments and Electrical Measurements*.—Switchboard, portable, standard, and absolute instruments. Testing and standardisation methods; absolute measurements. *Economics of Central Stations and Systems*.—Load factors, power factors, and all problems affecting the economy of central stations; also rates and regulation by public service commissions. *Electro-Physics*.—Radio-activity; Röntgen rays; gas and vapour conduction; electron theory; constitution of matter. *Miscellaneous*.—Such as history of literature of electrical engineering; symbols and nomenclature; engineering education and ethics. In each section it is desired to include Papers dealing with the status or the progress of the art. Offers of Papers and suggestions should be directed to the Secretary of the Committee on Organisation, Dr. E. B. Rosa, Bureau of Standards, Washington, D.C., U.S.A.

## STREET LIGHTING FITTINGS

IN a new list embracing numerous designs of weather-proof lanterns and street-lighting fittings just issued by Siemens Bros. Dynamo Works, Ltd. (Incandescent Lamp and Fittings Department, Tyssen Street, Dalston, N.E.), are some new designs of interior reflectors for the conversion of existing gas lamps to electricity. We illustrate in Figs. 1 and 2 two of the Company's registered designs which are made in white enamelled zinc, and, as may be seen, combine an efficient lighting fitting with the advantages of a cheap and easy method of converting gas lamps to electricity, using "Wotan" metal filament lamps. In

FIG. 1.—ENAMELLED ZINC REFLECTOR  
FOR USE IN GAS LAMP.

FIG. 2.—CONVERTED GAS  
LAMP.

Fig. 2 may be seen how neat is the appearance of one of these converted lanterns, with a D.P. switch inserted between the lamp standard and the lantern. Included with the well-known standard fittings supplied by the firm there is also the new Goliath Edison screw lamp-holder for use with high candle-power metal filament lamps on the "Brighton" series system (ELECTRICAL ENGINEERING, April 24th, p. 230). Although this fitting is fitted with a special shunting device to keep the circuit complete on the failure or withdrawal of the lamp, it is extremely neat, and is only 3 in. diameter by 4 in. deep.

## CATALOGUES, PAMPHLETS, &c., RECEIVED

**INSTRUMENTS.**—A new leaflet from Everett, Edgcombe & Co., Ltd., describes their new "disc" type, long-scale, moving-coil switchboard ammeters and voltmeters. The advantages of long-scale instruments such as these, with a scale embracing an arc of some 300 degrees, have been for some time recognised in connection with A.C. instruments, and are by the introduction of these instruments extended to continuous current, so that all the different class of instrument on a combined board can be uniform in appearance.

**FANS.**—A neat postcard, as shown by our illustration, in black and gold, depicting Ediswan fans, is being issued to the trade by the Edison & Swan United Electric Light Co., Ltd. (Ponder's End, Middlesex). Although the supply is necessarily limited, we understand from the Ediswan Co. that they will be pleased to send a supply of these cards, until exhausted, to any of their "Fan" customers, who have not already ordered any, if they mention ELECTRICAL ENGINEERING.

**FITTINGS.**—A new catalogue from Siemens Brothers' Dynamo Works (Incandescent Lamp and Fittings Dept., Tyssen Street, Dalston) deals with fittings for semi-indirect and inverted illumination, and contains a very tasteful selection of fittings for use with Opal, Holophane, Cervix, and Alabaster bowls, as well as inverted pendants in enamelled iron, in sizes suitable for all classes of buildings. The reflectors of the inverted fittings are of various forms, including steel and white enamel.

**WATERTIGHT TELEPHONES.**—The Siemens type of watertight, loud-speaking marine type telephone is described in a new list from Siemens Brothers & Co., Ltd. (Woolwich). Special deck and engine-room patterns are included with suitable selector switches.

**HOLOPHANE.**—A neat, comprehensive, and complete list giving particulars and prices of all present standard Holophane glassware, as well as a large variety of fittings specially designed for use with these shades, has been issued by the Sun Electrical Co., Ltd. (118 and 120 Charing Cross Road, W.C.).

**FANS.**—Another seasonable new list embracing electric fans of all kinds and accessories has also just been produced by this company, who will forward copies to any of our readers on request. Besides the many fans suitable for domestic, office, and industrial use, we notice the Sun special type of railway fan, which is supplied very largely to Colonial and foreign railway companies. As well as the ordinary desk and oscillating fans, a special feature is made of a combined fan and table lamp, and a combined fan and fruit dish.

*Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."*

**MERCURY VAPOUR RECTIFIERS.**—A list dealing with mercury vapour rectifiers for projection arcs for cinematographs, &c., has been sent us by the Westinghouse Cooper Hewitt Co., Ltd. (80 York Road, King's Cross, N.). The apparatus provides low voltage direct current for the arc while retaining the advantage of A.C. regulation, and the cost of the equipment is considerably less than that of a motor generator or rotary converter.

**TUMBLER SWITCH CONTROL.**—A second and enlarged edition of the special circular relating to the use of tumbler switches for the control of heating and cooking apparatus, by A. P. Lundberg & Sons (477 to 489 Liverpool Road, N.), which was first issued a year ago, has just made its appearance. Twelve distinct types of control are described, using series-parallel, two-way, "All-or-Part-and-off" switches, "Twinob" switches, and others developed by the company, giving various degrees of regulation. The switches are made in surface and flush patterns, the insulation is heat resisting, and the parts well made to withstand constant manipulation and prolonged currents. Special arrangements for pilot or tell-tale switches are also described, and the list concludes with illustrations of switch, plug, and combined switch and plug connections, specially suitable for radiator circuits, with or without extra earthing connections.

**BATTERY FANS, &c.**—Several types of small fans are described in a new leaflet from the General Electric Co., Ltd. (67 Queen Victoria Street, E.C.), suitable for driving from Edison-Lalande cells or accumulators. An attractive shop window novelty, consisting of two captive electrically driven model aeroplanes is also included.

**ELECTRIC SIGNS.**—Recognising the value of the illuminated sign as an aid to business, Siemens Brothers Dynamo Works, Ltd. (Incandescent Lamp and Fittings Department, Tyssen Street, Dalston), have got out a list of representative designs in classified sections, including special signs for theatres and cinematograph halls, compact signs for use on board ship, and hanging signs. These can be fitted with several varieties of glassware, but special reference should be made to "Opalex" glass, in which a special coloured ground can be fired on to a sheet of white opal glass. Cloisone and cloiglasic panels are used for more elaborate colour schemes. A number of different patterns of flashes are included.

**Dielectric Fatigue.**—A series of tests to determine the nature of dielectric fatigue in ebonite and presspahn, carried out at the University of Liverpool by W. Holtum, are contained in a Paper which has been accepted for publication in the Journal of the Institution of Electrical Engineers. The method adopted was to apply an alternating pressure to the sample under test for a certain time, and then to find a pressure which, applied for 0.1 sec. at 50 or 60 frequency, caused breakdown. This was taken as a measure of the instantaneous strength. The switching operations were carried out automatically, and a large number of samples were tested. The general conclusions deduced are: (1) That fatigue due to electric stress alone is almost negligible for ebonite and presspahn until the point of breakdown is approached, the greatest amount measured for ebonite being 2 per cent. of the initial instantaneous strength. (2) That the least pressure which will cause breakdown if applied continuously is about 80 per cent. of the lowest measured value to which the instantaneous strength can be reduced by fatigue. The conclusion of greatest practical importance is that the dielectric strength of ebonite for sudden stresses lasting for a fraction of a second is only some 28 per cent. greater than it is for long-continued stress, and that any ebonite used for insulation purposes should be designed for the greatest pressure which may occur as though that pressure were continuous.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,346.

Describe a regular course of routine inspection and testing for a central station battery of about 250 cells of say 1,000 ampere hours' capacity at the five hour rate; (a) with end regulating cells, and (b) without end regulating cells.—"NASCENT HYDROGEN."

(Replies must be received not later than first post July 17th.)

### ANSWERS TO No. 1,344.

In what way can the forces on transformer coils due to short circuit be determined in three-phase core type and single-phase shell type transformers with sandwich windings?—J. W.

The first award (10s.) is made to "ALPH," for the following reply:—

The mechanical forces due to leakage flux tending to wreck a transformer on short circuit may be divided into three classes: (1) Leakage flux bridging between two faces of the core tends to draw these faces together. This may be neglected, since the core will always be sufficiently strong to prevent any appreciable distortion. (2) Leakage flux encircling one or more coils tends to compress the coil or to draw together its component parts if it is split into sections. This effect is sometimes observable in a transformer which has withstood a short circuit, but it is not usually sufficient to cause damage. (3) Leakage flux between two coils exerts a compressive force at right angles to the direction of the flux, tending to separate the coils. This is the force which usually proves destructive to the transformer by bursting the coils apart.

The stresses due to a magnetic field, both the tension in the direction of the lines and the compression at right angles to the lines, can be calculated from the well-known formula,  $S = B^2/8\pi$ . Where  $S$  is the stress in dynes per sq. cm., and  $B$  is the flux density in lines per sq. cm. Also

$$B = \frac{4\sqrt{2} \times \pi N I \mu}{10L}; \text{ where } B = \text{max. flux density in lines per}$$

sq. cm.,  $N$  = effective number of turns,  $I$  r.m.s. current in amperes,  $\mu$  = permeability of circuit, and in air is unity;  $L$  = length of path in cms. The factor  $\sqrt{2}$  is, of course, the ratio of the maximum current to the r.m.s. current, and is strictly only applicable to a sine wave. It may, however, be taken as sufficiently accurate in most cases, but if the current wave is very much distorted the maximum value of current should be used instead of  $\sqrt{2}I$ . Combining these formulæ and converting to English measure we have,  $S = \frac{2.82 \times 10^{-7} N^2 I^2}{L^2}$ ,

where  $S$  is the maximum stress in lbs. per sq. inch, and  $L$  = length of gap in inches, measured in the direction of the lines of force.  $NI$  must be determined for each gap between primary and secondary windings, by taking the algebraical sum of the various ampere turns assisting and opposing the resultant leakage flux in the gap in question. The maximum

pressure on the coils on each side of the gap is  $SA$ , where  $A$  is the area of the face of the coil in square inches, i.e.,  $A = LL'$ , where  $L'$  is the length of the portion of the coil under consideration, measured along the conductors, and  $L$  is the length of the gap in the direction of the lines of force, which run at right angles to the conductors. The resultant pressure tending to bend any coil is the difference between the pressures calculated for the gaps on each side of the coil, for that portion of the coil which lies outside the core. The pressure tending to burst apart the ends of the core is  $P = S_{\text{max}} ML$ , where  $S_{\text{max}}$  is the stress in the gap for which  $NI$  is a maximum, and  $M$  is the mean length of one turn of the winding,  $L$  being the length of gap as above.

It will be seen that the mechanical forces acting on the transformer are proportional to the square of the current, and it is therefore necessary to determine the maximum current which can flow on short circuit. If the capacity of the supply system is very large compared with that of the transformer, and the line between generators and transformer is short, the current flowing in the event of a short circuit at the secondary terminals will be limited only by the impedance of the transformer. Assuming this is 3 per cent., the short-circuit current will be thirty-three times the full-load current, and the forces acting on the windings 1,100 times those at full load. This is, however, the worst possible case, and as a rule there will be a drop in voltage due to the overload on the generators, as well as a drop in the line. The simplest way to take this into account is to assume a probable value for the short-circuit current and calculate the volts drop in generators and line for this current. The resultant voltage at the transformer terminals, divided by the transformer impedance, gives a closer approximation to the true short-circuit current, which can be used as a basis for working the calculation through again, if the current assumed in the first instance was very far from the true value.

From the above, the stresses in the single-phase shell-type transformer can be readily calculated. In the case of the core-type transformer it will be seen that if the primary and secondary windings are concentric and symmetrical (as is probably the case), the forces due to the leakage flux merely tend to expand the outer winding and compress the inner. The compression will be taken by the solid core, and it is unlikely that the tension in the outer winding will reach a dangerous value. It may, however, be calculated from  $S_t = \frac{4.5 \times 10^{-8} N^2 I^2 L_1}{aL}$ , where  $S_t$  = tension stress in the copper wire,  $L_1$  = length of inside turn of outer winding,  $a$  = total section of copper in outer winding, and the other symbols have the same meaning as before.

It should be noted that the actual forces are not steady, but vibratory, varying from the maximum values calculated as above to zero twice in each cycle. If the natural frequency of vibration of any part of the transformer (such as the portion of a coil projecting beyond the core, for instance) should happen to be the same as the frequency of the stress, i.e., twice the supply frequency, a condition of resonance would be established, giving rise to forces very much higher than the calculated value—theoretically infinitely great. It is practically impossible to guard against this contingency, on account of the impossibility of determining the natural frequency of vibration of the various parts of the transformer, but it may very probably explain the occasional failure of a transformer to withstand short-circuit currents which on calculation appeared well within the limits of safety.

**University College Entrance Scholarships.**—The Entrance Scholarships in the Faculty of Engineering awarded to Messrs. C. H. Avery and G. G. Dawson have been renewed for a further year, as has also the Goldsmid Scholarship that was awarded to Mr. P. L. Capper. The Archibald P. Head Medal and Prize goes to Mr. W. J. Duncan. The following students have obtained Engineering Diplomas:—Messrs. L. S. B. Alder, P. R. Coursey (with distinction), A. M. Fahmy, D. W. Fletcher, D. N. Gautam, A. F. Gimson, A. F. Hewett, E. W. A. Hunt, N. R. Kapur, N. F. Kelsey, B. G. G. Manton, A. El R. Orfy, L. J. Powis, C. H. E. Ridpath, M. H. Schwab, and R. T. Singh.

## "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

### Specifications Published July 3rd, 1913

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

10,338/12. **Joining Tungsten to Copper.** B. T.-H. Co. (G.E. Co., U.S.A.). The copper is purified by treating at a temperature considerably above its melting point with an oxidisable boron compound, and then melted or cast in contact with the tungsten.

14,088/12. **Automatic Motor Starters.** F. BROADBENT. In starters in which the rheostat arm is first moved by hand into the full resistance position and then allowed to return automatically, "inching" movements at starting are obtained by an auxiliary switch governed through a pilot switch or push-button, without it being necessary for the rheostat arm to be clear of the starting resistance studs. This switch may be in parallel with the contacts controlling the auxiliary switch, so that the actual "inching" is controlled by the rheostat arm, or it may be placed near the topmost position of the rheostat arm so that it can be operated intermittently without releasing this, or the magnet coil of the auxiliary switch may be connected across the mains through the "inching" switch, which is normally open and controls a branch of the main circuit connected with the starting resistance. Three figures.

14,161/12. **Coupling Metallic Tubing.** G. P. M. LEE and W. A. BRAME. To couple metallic tubing together or to a fixed casing, an open helix of steel or other strong wire is used. The tubing is screwed into this and soldered. Four figures.

14,236/12. **Commutating Dynamos and Motors.** M. DÉRI. Sparkless commutation is obtained by arranging pairs of brushes so as to prevent the armature coils from being directly short-circuited. The brushes for each pair of poles are kept connected to an external circuit, in which are produced alternating pressures of the frequency of commutation. To effect this an auxiliary machine having coils inserted between the two brushes of every pair, and acted on inductively by a field energised from the main current, may be used with or without condensers. Other ways, using transformers as well as auxiliary machines, are also described. Ten figures.

15,275/12. **Heating Element.** SIMPLEX CONDUITS, L. M. WATERHOUSE, and T. BIRKETT. Two insulating strips, the central portions of which are held a fixed distance apart by a longitudinal separator, over which is wound transversely a resistance ribbon sufficiently taut to elastically bend the strips and bring their longitudinal edges together, thus forming a resilient core. The strips may be of mica, and the separator of metal. Twelve figures.

17,386/12. **A.C. Current Limiter.** A. W. ASHTON. A choking coil is connected in series with the consumer's circuit to effect a reduction in the supply pressure when a predetermined maximum load is reached. The coil has a tapering air-gap closed by a spring when the flux reaches a certain amount, so that the self-induction is increased. As the permissible load may be different at different times, this may be allowed for by altering the reluctance of the coil by a clock-driven iron disc which partially closes the air-gap at predetermined times.

17,838/12. **Self-Regulating Dynamos.** C. A. VANDERVELL and A. H. MIDGLEY. Main and supplementary poles and brushes are used. The windings on the supplementary poles are connected to a main and supplementary brush, arranged to span the armature conductors under the supplementary pole, so that a field opposing but less than the armature cross-field under the main poles is produced. Seven figures.

### Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** TAYLOR [Fault clearing on A.C. systems] 16,830/12.

**Dynamos, Motors, and Transformers:** LAKE (*Le Carbone Co.*) [Brushes] 24,343/12; SIEMENS DYNAMO WORKS, KIEFFER and PARKER [Ventilating] 3,224/13.

**Electrometallurgy and Electrochemistry:** JOHNSON [Welding] 14,145/12; HÉROULT [High-grade pig iron] 25,858/12.

**Heating:** VON HENTZEL [Liquids] 28,359/12.

**Ignition:** LAWRENCE [Driving rotary magnetos to facilitate engine starting] 14,324/12; BROOKS and HOLT [Motor vehicle ignition and lighting] 18,764/12; HARTMANN & BRAUN [Magnet] 19,913/12; JUSTICE (*North East Electric Co.*) [Engine starter] 28,930/12.

**Incandescent Lamps:** FARKAS [Drawn wire lamps] 14,655/12; HANSEN and MOHR [Boron-tungsten compound] 3,525/13.

**Instruments and Meters:** DAVIS and HUNTER, 14,576/12; LANDIS & GYR [Two-rate meters] 22,592/12; SCHOLLER [Meter] 24,954/12.

**Switchgear, Fuses, and Fittings:** HARRIMAN and A. REYROLLE & Co. [Dash-pots] 13,997/12; LEITNER [Switches] 14,270/12; SIEMENS BROS. and GRINSTED [Electro-magnetic relays] 14,564/12 and 28,824/12; ELECTRIC & ORDNANCE Co. and COX [Resistance grids] 20,252/12; FISCHER [Mica plates for resistances] 23,869/12; HUTTMANN and HABERL [Time switches] 25,787/12; BOSCH [Automatic regulators] 27,961/12.

**Telephony and Telegraphy:** CRAVEN [Switchboard connecting cords] 11,306/12; HINZPETER [Telephonically ordering cabs, messengers, &c.] 13,807/12; AUTOMATIC TELEPHONE MFG. Co. (*Automatic Elec. Co., U.S.A.*) [Telephone systems] 13,970/12, 13,971/12, 13,972/12, 13,973/12, 13,974/12, and 13,975/12; AITKEN [Telephone sub-station switching] 14,317/12; ZIVNOTSKA BANKA V. PRAZE [Subscribers' automatic telephone stations] 16,374/12; CIE GENERALE RADIOTELEGRAPHIQUE [Charging condensers in parallel and discharging in series] 29,375/12; GRASME [Mechanical type-printing telegraphs for toys] 4,665/13.

**Traction:** HAWORTH and THOMAS TRANSMISSION, LTD. [Control and use of series dynamos] 14,396/12.

**Miscellaneous:** MASCHINENBAU-ANSTALT HUMBOLDT [Rotary annular multipolar magnetic separators] 9,147/12; BRETTLELL (*Martenson*) [Light diffuser] 14,192/12; THOMSON and ROTHWELL [Miners' safety lamps] 14,202/12; GOY [Massage device] 18,271/12; TURNER [Portable electro-medical appliance for use in the bath] 22,807/12; SIEMENS & HALSKE [Refractory articles of tantalum] 23,050/12; JUSTICE (*North-East Electric Co.*) [Power gearing] 28,931/12; STERN and BRITISH EVER READY ELECC. Co. [Portable lamps] 29,302/12; BARES and WEISS [Fire and burglar alarm] 1,285/13; ELECTROMECHANISCHE INDUSTRIE GES. [Pocket lamp and compass] 5,646/13; ELECTROMOTOR EQUIPMENT Co. and MEACOCK [Gearing] 8,503/13.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Incandescent Lamps:** GRAMMONT [Tortuous filament] 13,632/13.

**Meters:** SCHOTT & GEN [Electrolytic] 10,512/13.

**Switches:** FAGERLUND, 13,654/13.

**Miscellaneous:** FORSTER [Friction couplings] 13,308/13.

### Grant of Patent Allowed

10,600/12. **Footstep for Telegraph Poles.** H. LENCH. The grant of the patent has been allowed, in spite of opposition.

### Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:—

14,304 of July 11th, 1899. **Electric Automobiles.** W. P. THOMPSON (*E. Cantono, Italy*). The system described is based on the employment of the "Cantono" flat-ring inductor motors described in specifications Nos. 25,245/97 and 3,218/98, with variations in the intermediate plate obtained by slight variations in the excitation. The motors (two per axle) can be connected, so that each shaft independently actuates a motor wheel by means of gearing; or the two motors can be separate, each actuating a motor wheel through worm and spurwheel gearing. This method is preferable for driving heavy vehicles, such as omnibuses. The worm has four or five threadings, with a progression equal to the diameter, whereby a high efficiency is obtained, and the motors can act as electric brakes. The worm is keyed on the shaft, and is movable longitudinally, being held in place by two springs, so that the wheel is not rotated until one spring is compressed till its reaction is stronger than the resistance to the road wheel. Three figures.

The following are the more important Patents that have become void through non-payment of renewal fees.

**Distributing Systems, Insulating Materials, &c.:** C. J. BEAVER and E. A. CLAREMONT [Insulating materials, &c.] 6,708/07.

**Dynamos and Motors:** MATHER & PLATT, E. HOPKINSON, and J. FRITH [Polyphase induction motor with several rotors and two stators, the magnetic field being made to progress oppositely in the two stators] 5,899/05; A. WIGH [Wheel-driven dynamos for vehicle and motor-boat lighting, &c.] 5,972/08.

**Electrochemistry:** G. J. ATKINS [Obtaining chlorine by electrolysis of an alkaline earth chloride] 5,596/01; N. J. NIELSEN [Regulating high-pressure milk sterilisation] 5,776/05.

**Switchgear and Fittings:** G. H. IDE [Cord grip] 6,310/08.

**Telephony and Telegraphy:** S. EVERSHED and EVERSHED & VIGNOLES [Ships' telegraphs for gunnery purposes] 5,903/01.

**Miscellaneous:** W. G. HEYS (*J. Scott, R. Farley and J. C. Anderson, U.S.A.*) [Winding coils of bare wire and insulating with threads and paper] 5,257/00; MÄRKISCHE MASCHINENBAUANSTALT. L. STUCKENHOLZ [Lifting magnets] 21,030/07.

LONDON

## ELECTRIC TRACTION NOTES

An agreement is said to have been arrived at between the Metropolitan and Great Northern Railway Companies for the joint control and working of the Great Northern and City Tube Railway. It is anticipated that physical connections will be made between the Great Northern system and the Tube railway at Finsbury Park, and with the Metropolitan line at Moorgate Street. One of the drawbacks to the financial success of the Great Northern and City Railway has been the one of a physical connection with the Great Northern system at Finsbury Park, which was originally anticipated when the line was first built, but which, for obvious reasons, was never given effect to.

The point as to whether a tramway sanctioned under the Light Railways Act is liable to be rated as a tramway or a railway for purposes of local taxation has been discussed at considerable length before the House of Lords. The case in question was the final appeal in the action taken by the Tottenham Urban District Council against the Metropolitan Electric Tramways, Ltd. The Local Justices, and subsequently a Divisional Court, held that the lines in question did not come within the definition of a railway, and ordered the company to pay rates on the full assessable value of the undertaking, and not upon a quarter, as in the case of a railway. The Court of Appeal, however, subsequently reversed this decision, and it is against this that the Tottenham Council is now appealing to the House of Lords. Judgment will be given later.

Owing to the small net surplus upon the London County Council tramways last year, namely, £497, the Highways Committee reports that it is unable to make the usual provision for renewals at the rate of 3d. per car mile. It recommends that the amount available this year should be transferred to the renewals fund, and that any rearrangement of the basis of contribution to this account be postponed for two years.

As a result of the recent discussion upon electric battery vehicles at the I.M.E.A., Alderman Fred Smith, Chairman of the Liverpool Tramways Committee, has been instrumental in securing an investigation into the possibilities of this method of traction in Liverpool. The General Manager of the tramways system has to report as to the use of this method of traction in connection with the docks.

The members of the Metropolitan Association of Electric Tramway Managers entertained Mr. H. E. Blain, their late chairman, to dinner at the Municipal and County Club on Friday evening last.

## TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

Considerable dissatisfaction has been caused by the imposition of a fee of one guinea by the Post Office for the issue of licences for experimental wireless telegraphy. Under Clause 2, sub-section 1, of the Wireless Telegraphy Act of 1904 it is expressly provided that licences to conduct experiments in wireless telegraphy shall not be subject to any rent or royalty. The Post Office is apparently trying to get out of this by calling the guinea which they charge a fee for office expenses in connection with the issue of licences, and we understand that they have taken legal advice as to whether they are entitled to make this charge. Although it is not a serious burden upon the majority of *bona fide* investigators who wish to conduct a series of experimental researches in wireless telegraphy, and is presumably intended principally to discourage the amateur, yet it is to be regretted that the Post Office should adopt a course which certainly evades the spirit of the Wireless Telegraphy Act, although it is not in conflict with the letter of it.

On Friday last a petition was presented to the Judicial

Committee of the Privy Council by the Australian Government through Mr. Danckwerts, K.C., and Mr. E. A. Harney, K.C. (Australia). Special leave was sought to appeal from the order of the Australian High Court permitting an inspection by the Marconi Co. of the Australian wireless stations, in connection with their action for infringement against the Australian Government, which claims to be working a system under the patents of Mr. Balsillie. Mr. Danckwerts urged that the matter of law involved was of great public importance. This was whether the opinion of a responsible Minister of the Crown was conclusive, or whether it could be examined by the Court. The majority of the Australian Court inclined to the latter view, and thought that there could be nothing to warrant even a conjecture that the inspection would disclose anything which could reasonably be called a State secret. Without calling on Mr. A. J. Walter, K.C., and Mr. J. Hunter-Gray, who represented the Marconi Co., the Lord Chancellor said that this was not a convenient case to discuss the matter of law raised, and they must refuse the petition.

In announcing to a deputation from the London Chamber of Commerce last week that he will shortly ask Parliament for authority to borrow £10,000,000 for the development of the Post Office telephone system, the Postmaster-General emphasised the point that in his opinion the complaints against the telephone service since it has been in the hands of the Government have been considerably exaggerated. Among the developments foreshadowed is the spending of £300,000 on a new underground cable from London to Birmingham.

In the House of Commons last week the Postmaster-General announced that the price agreed with the National Telephone Co. for the purchase of their undertaking is £12,470,300, or £45,000 less than the amount actually awarded by the arbitrator. On the other hand, the Post Office has, it will be seen, abandoned its claim with regard to the item of £247,200, the cost of raising capital, which, it has been suggested, should have been deducted from the award.

The Post Office has been negotiating the terms of a new agreement with the Marconi Co. for the Imperial wireless telegraph scheme. This will involve an additional expenditure compared with the old contract, due, in the first place, to the increased cost of materials necessary for the equipment of the stations, which the Company estimates at about £6,500 per station. Briefly, the other alterations in the old contract are that 10 per cent. royalty is to be paid the Company for each station separately, such royalty to be paid only in respect of the receipts of those stations where Marconi patents are to be used. The Government have the right to instal other apparatus in the stations even before the completion of the first six stations. On the other hand, the Company, which had previously guaranteed the speed of transmission of fifty words a minute by automatic apparatus, now guarantees seventy-five words a minute. With regard to the right of the Company to inspect any plant installed by the Government which it is suspected infringes their patents, such inspection is now to be made by an independent engineer. The new contract provides for the construction of the stations by the Company, the Government holding the view that the only alternative was the creation of a new staff, and the employment of an engineer of distinction to supervise the work. This, however, it was not felt the Government could undertake. The contract is not to be binding unless ratified by the House of Commons before August 31st this year.

It is stated that the Danish Naval authorities will adopt the Poulsen wireless telegraph system in the Danish Navy.

Sitia-Rhodes cable failed on the 2nd inst., and was repaired on the 5th.—The Servian authorities announce that telegrams for Salonika may not pass over their territory, while the Roumanian Government has suspended all private telegraphic intercourse in code or cipher language.—The Fort-de-France Paramaribo cable of the French Cable Co. failed once again on the 3rd inst, but it was put in order again on the 7th inst.—The Bulgarian Administration has prohibited the exchange of telegrams with their office at Salonika.—Newfoundland has become an official adherent to the Radiotelegraphic Convention of Berlin.

## LOCAL NOTES

**Bootle: New Power Station.**—The new power station is approaching completion. The Committee has decided to postpone any revision of tariffs until the new works have come into beneficial use.

**Bradford: Electrical Developments.**—In view of the important developments in the near future in the Bradford electricity undertaking, the members of the Electricity Committee have recently been inspecting the Manchester power stations.

**Electricity Accounts.**—There was a net profit of £8,477 upon last year's working on the electricity undertaking.

**Bridlington: Electricity Accounts.**—There was a net profit of £1,825 upon the electrical undertaking last year. In spite of the extra coal costs the total cost of production was slightly decreased, compared with the previous year. The sum of £500 to be transferred to renewal fund from the profit for the year.

**Dalkey: Electric Supply.**—The Alliance and Dublin Consumers' Gas Co. intends to apply for electric lighting provisional orders for a number of towns, including Dalkey.

**Dudley: Sale of Electrical Undertaking.**—We pointed out a short time ago that a difficulty had arisen in connection with the sale of the electrical undertaking to a private company, inasmuch as under the terms of the proposed sale the rates of the Borough would still be liable, in the event of failure on the part of the purchasing company, to repay the outstanding loans on the undertaking. The Company has now offered the Council certain securities in this matter, which the Council are being recommended to accept by the Electric Supply Committee.

**London: Hammersmith: Electricity Accounts.**—The sum of £2,500 is to be carried to reserve from the electricity accounts for last year, and provision is also to be made out of the profits of £4,540 for £300 for conversion of gas lamps and £300 for an electrical exhibition to be held later.

**Hampstead: Electricity Accounts.**—In view of the expansion of the Council's electricity undertaking, it has been decided to engage a firm of chartered accountants at a fee of 100 guineas per annum to report quarterly upon the accounts.

**St. Marylebone: Electricity Accounts.**—The past year's working of the electricity undertaking shows a net profit of £4,014. This is about £2,800 less than was estimated for at the beginning of the year, but the Finance Committee, in reporting upon the situation, thinks the Council is to be congratulated upon the results, in view of the advance in the cost of fuel, which exceeded the estimates by £4,500, and is an increase of £6,600 in actual expenditure compared with the previous twelve months.

**St. Marylebone: Electric Cooking Apparatus.**—In connection with the regulation which the Board of Trade proposes to prescribe with respect to the supply of energy at medium pressure for cooking purposes, the London County Council has expressed the opinion that the framework of cooking apparatus, as well as the guard protecting the heating elements, should be efficiently earthed.

**Tottenham: Gas Company's Electric Powers.**—The bill of the Tottenham and Edmonton Gas Co., which transfers the Wood Green Council's electric lighting order to the Company, has now passed through both Houses of Parliament. The North Metropolitan Electric Power Supply Co. and the North Metropolitan Electric Power Distribution Co. endeavoured to oppose the bill at various stages, but both in the House of Commons and in the House of Lords they were refused a locus.

**Middleton: Street Lighting.**—The lighting of the centre of the town is engaging attention, and further additions to the electric lighting of the streets are contemplated.

**Newcastle-under-Lyme: New Plant.**—Two Diesel engines have been installed and are now running daily with very satisfactory results. The supply was changed over to the three-wire system in Whitsun week, and a supply at both 460 and 230 volts is now being given.

**Sunderland: Electricity Accounts.**—The report of the Borough Electrical Engineer for the year ended March 31st shows a net profit of £6,248, which would, however, have been considerably more but for the effects of the coal strike. The net profit is to be carried to depreciation and renewals fund. Dealing with the disposal of the steam generating plant in the Dunning Street works, and the disused continuous-current generating plant at Hylton Road, the report

points out that the original cost of this was £64,927, whilst the outstanding debt upon it at March, 1912, was £31,255. Towards this the sinking fund is to contribute £2,186, and £5,069 is to be taken from depreciation and renewals fund. Adding to this the estimated amount to be realised by the sale of the plant, namely, £7,250, there will remain an outstanding book debt on the plant of £16,750.

**Weston-super-Mare: "Stealing" Electricity.**—The proprietor of the flying machine who resorted to the practice of connecting his lighting circuits to his power meter, in order to get current at the cheaper rate, as reported in our last issue, has been fined £10.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

## Generating Stations, Sub-Stations, Mains, &amp;c.

**Belfast.**—A loan of £35,000 for electrical extensions is to be applied for.

**Cardiff.**—A loan of £30,000 is to be applied for in connection with extensions at the electricity works.

**Darwen.**—The sanction has been given to a loan of £3,572 for mains, &c.

**Durham.**—An electric lighting plant is required for the Richard Murray Hospital, Blackhill, Co. Durham. Secretary.

**Hamilton, N.B.**—Additions to electricity works, at estimated cost of £10,000.

**London: L.C.C.**—High and low-tension sub-station switchgear. (See an advertisement on another page.)

**Battersea.**—Mains extensions at an estimated cost of £2,179 are to be carried out.

**Loughborough.**—Loans of £11,000 for plant, and £3,000 for mains are to be applied for.

**Manchester.**—Borrowing powers have been sanctioned for £45,000 and £30,000 for electricity purposes.

**Newport (Mon.).**—Extra high-tension switchgear. Borough Electrical Engineer, July 19th.

**Perth (W.A.).**—Switchgear and accessories are required for the municipal power station. Particulars from Consulting Engineers, Messrs. Merz & McLellan, 52 Victoria Street, London, S.W.

**Peterborough.**—Sanction has been received to the borrowing of £7,000 for a new generating set, boilers, &c.

**Rochdale.**—Sanction has been given to a loan of £30,000 for extensions at the electricity works.

**Sheffield.**—An inquiry was held last week concerning a loan of £130,860 for the electrical undertaking. During the course of the proceedings it was stated that the demand for power purposes has increased from 868,943 units in 1904, to 16,717,000 at the present time. In addition to the remarkable increase now taking place, both in the lighting and power demands, the installation of electricity for street lighting is under consideration.

**Shipley.**—Two 1,000-kw. steam turbo-alternators with surface condensers and switchboard. (See an advertisement on another page.)

**South Shields.**—New generating plant, estimated to cost £30,000, is to be installed.

**Stoke-on-Trent.**—Mains extensions, at an estimated cost of £1,555, are to be carried out.

**York.**—A proposal has been made to extend considerably the limits of supply for electricity purposes.

An expenditure of £16,450 is contemplated upon street electric lighting works.

The City Electrical Engineer has reported that the cost of laying mains throughout the city for domestic purposes would be £100,000. The Electricity Committee, however, recommend that extensions be made from time to time.

### Wiring

*The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.*

**Barnsley.**—Variety theatre. Architect, P. A. Hinchcliffe, 14 Regent Street.

**Barrow-in-Furness.**—New secondary school.

**Blackburn.**—New fire station and firemen's dwellings.

**Brighton.**—School Hall, Brighton College (£6,000).

**Croydon.**—Thirty-eight houses in Ashburton Avenue. W. Nottle, 250 Albert Road. Thirty-two houses, Compton Road. C. D. Gooch, 54 Gresham Street.

**Darwen.**—Cinema theatre in Bolton Road.

**Doncaster.**—Block of offices, corner of French Street. Borough Surveyor.

**Gomersal.**—Reconstruction of Gomersal Mills. T. Barnsley & Sons. Architect, C. D. Swale, 5 Cabinet Chambers, Leeds.

**Greenock.**—Electric lighting of Highlanders' Academy. Consulting Engineer, T. C. Fulton, 143 West Regent Street, Glasgow.

**Kingston-on-Thames.**—Alterations to St. Luke's Schools. Borough Surveyor.

**Leeds.**—Offices for Board of Overseers. Architect, A. Neill, 38 Park Row.

**London:** L.C.C.—235 points, Tollit Street School, Mile End. (See an advertisement.)

**Middleton.**—Extensions to the Rhodes Council School. Borough Surveyor, July 4th.

New Town Hall (£30,000).

**Sale.**—New Council Offices.

**St. Helens.**—Municipal hall and fire station.

**Southend.**—Alterations and additions, Leigh Road School. Borough Engineer.

**South Wales.**—Capel Hotel, Bargoed. Architect, S. Williams, Wharton Street, Cardiff.

**Watford.**—Working-class houses.

### Miscellaneous

**Australia.**—It is stated that Mr. R. P. Wilson has reported with reference to the electrification of the Perth-Northam section of the Trans-Continental Railway through the Darling Ranges.

105 miles lead-covered paper-insulated cable. Deputy Postmaster-General, Melbourne, August 19th. Particulars from High Commissioner, 72 Victoria Street, S.W.

**Malta.**—Supply of arc lamp carbons. Crown Agents for Colonies, Whitehall Gardens, S.W.

### TENDERS RECEIVED AND ACCEPTED

**Belfast.**—The tender of the Sturtevant Engineering Co. has been accepted for wet air filters at £369.

**London: Hammersmith.**—The following tenders have been received for ten 100-kw. transformers and five 50-kw. transformers:—Johnson & Phillips, £79 each and £46 17s. 6d. each respectively; British Electric Transformer Co., £85 and £50 5s.; W. E. Burnand & Co., £87 10s. and £54; Brush Electrical Engineering Co., £93 10s. and £56 12s. 6d.; Foster Engineering Co., £94 and £47 10s.; Ferranti, £94 and £60; Electrical Engineering & Equipment Co., £105 10s. and £59; British Westinghouse Electric & Manufacturing Co., £141 and £83 10s. The tender of the British Electric Transformer Co. is recommended for acceptance in both cases.

**Peterborough.**—The tender of Messrs. F. Danks & Co., of Oldbury, for the supply of a steam boiler, at £1,162 15s., is recommended for acceptance.

**Regina (Canada).**—The City Commissioners of Regina, Saskatchewan, have just ordered from Messrs. Bruce Peebles & Co. a 1,200-kw. motor-converter (Peebles' La Cour Patents).

**West Hartlepool.**—The tender of the British Thomson-Houston Co. has been accepted for rotary-converters in connection with the tramway supply.

### APPOINTMENTS AND PERSONAL NOTES

Mr. George Westinghouse, of the Westinghouse Co., Pittsburgh, has been presented with a gold medal by the Verein Deutscher Ingenieure, in recognition of his pioneer engineering work, in particular in connection with the "Westinghouse"

air brake. Mr. George Westinghouse is now President of thirty companies employing some 50,000 workers, and having a total capital of about £24,000,000.

Mr. R. N. Mayne, Deputy Electrical Engineer to the Erith Urban District Council, has been appointed Manager of the Redditch Electricity undertaking.

Mr. Alexander Pratt, of Edinburgh, has been elected President of the Electrical Contractors' Association of Scotland.

Mr. A. G. Cross, of the Newcastle-on-Tyne Electric Supply Co., has been appointed shift engineer at the Avonmouth sub-station of the Bristol Corporation.

Mr. J. S. D. Moffat, General Manager of the Rochdale Corporation Tramways, has been appointed to succeed Mr. H. E. Blain as General Manager of the West Ham Corporation Tramways.

Mr. W. E. Hart, Solicitor to the National Telephone Co. up to the time of its absorption by the Government, has been appointed Town Clerk at Sheffield in succession to the late Mr. R. M. Prescott, at a salary of £1,250, rising to £1,500 per annum.

A car shed electrician is required by the Ipswich Corporation tramways department. (See an advertisement on another page.)

### MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. G. Smith & Son, of 5 Philpot Lane, E.C., informed us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £67 10s. to £68 (last week, £67 10s. to £80).

**Change of Telephone Number.**—The telephone number of Scholey & Co. (151 Queen Victoria Street, E.C.) has been changed to City 5863 (two lines).

**Annual Outings.**—The employees of Page & Miles, Electrical Contractors, of Brighton and Worthing, held their annual outing on Saturday, when they journeyed by motor coach to Fittleworth, where very successful sports were held.

The Head Office Fire Brigade of the General Electric Co., Ltd., held their first annual outing at Windsor on Saturday last.

Nearly a thousand employees of the Western Electric Co. had an enjoyable outing at Herne Bay last week.

**Australian Agency.**—The principal of a Sydney firm, now in London, wishes to get into touch with the United Kingdom manufacturers of all kinds of electrical goods and machinery. Further particulars from London Chamber of Commerce, Oxford Court, Cannon Street, E.C.

**Liquidations.**—Creditors of the Doncaster Electrical Co. are requested to send in particulars of their claim to A. E. Stringer, Manor Row Chambers, Bradford, by July 21st.

**Change of Title and Address.**—The technical department of the business of Marcus Heber Smith, formerly carried on at 4 Racquet Court, Fleet Street, E.C., and managed by Mr. A. J. Greenly, is now being carried on under the style of Robinson, Greenly & Co., at 116 Charing Cross Road, W.C.

### COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

**General Electric Co.**—The available profit for the year to March 31st, including £32,050 brought forward, is £177,311. After setting aside £32,543 for debenture interest and depreciation, and paying the 6 per cent. preference dividend, a 10 per cent. dividend is recommended on the ordinary shares, transferring £50,000 to reserve, and carrying forward £32,331. The company's works have been fully employed throughout the year, and further extensions are contemplated, and the directors draw attention to the continued expansion of the business.

**Electric Construction Co.** A dividend of 5 per cent. is recommended on the ordinary shares for the year to May 31st, transferring £10,691 to general reserve, and carrying forward £6,899. The company's position has considerably improved during the past two years.

**Edmundson's Electricity Corporation.**—The net profit for the year to March 31st was £18,899, and after meeting the 6 per cent. preference dividend, the balance of £6,899 is carried forward.

### SUMMARY

It is expected that one or possibly two makes of very high candle-power (5,000—10,000) metal filament lamps, with an efficiency of  $\frac{1}{2}$ -watt per Hefner candle-power, will make an appearance this autumn. There is no question of lamps of any smaller candle-power being placed on the market at this efficiency. (Page 416.)

AGENTS have been appointed in England for the American National Board of Underwriters, so that apparatus to be supplied under the National Electric Code to Canada can be inspected and passed in this country. (Page 416.)

THE London electric supply companies are opposing the Post Office tube railway on the ground that it gives the Postmaster General powers to compete with the companies for the supply of electricity to post offices all over London. (Page 416.)

THE exhaust steam station at West Hartlepool is just being put into commission. It is interesting in that it is the first waste-heat generating station in the country to be run by a local authority, and also for the fact that Rosenberg self-starting rotary converters are used in the sub-stations. Current is generated by two alternators of 1,250 k.v.a. capacity at 6,000 volts. (Page 417.)

A NEW intercommunication telephone working entirely by push-buttons is described and illustrated. (Page 418.)

A DESCRIPTION of the "Knight" open or closed circuit public fire alarm system is given in a Paper published in the *Journal* of the Institution of Electrical Engineers. The system is very comprehensive. (Page 422.)

AN automatic star-delta starter is described. (Page 423.)

DETAILS are given of a wireless receiving outfit specially designed for the reception of international time signals by clockmakers. (Page 423.)

THE patent specifications published last Thursday include one for electric braking arrangements for the "Thomas" transmission by H. F. Haworth and the Thomas Transmission, Ltd., two relating to metal filament lamps by K. Farkas, and F. Hansen and W. F. Mohr respectively. A new design of the mechanism of moving iron instruments is also protected by W. J. Davis and C. E. Hunter, of the Ediswan Co. A method of charging condensers in parallel and discharging in series for wireless working is described in a specification by the Cie Générale Radiotélégraphique. Two important patents for flaming arc carbons taken out by H. Bremer expire to-day after a full life. (Page 424.)

A QUESTION of interest to shift engineers in central stations is propounded in our Questions and Answers columns. (Page 423.)

AN illustration is given of a telephone exchange switchboard which is being shown at the Ghent Exhibition. (Page 425.)

THE acquisition of the Great Northern and City Tube Railway by the Metropolitan Railway Co., the enlargement of the tunnels of the City and South London Railway, and the running of trolley 'buses from Wood Green to Walthamstow have all been sanctioned during the week by Parliament.—The Croydon Tramway Manager is urging Members of Parliament to consider the necessity of legislation for compelling motor omnibus companies to be placed on the same terms as tramway companies as regards road maintenance, &c.—We give some particulars of the work for the sub-station, on the Melbourne suburban railway system, which has been awarded to Messrs. Siemens Bros.' Dynamo Works. (Page 424.)

A LARGE number of questions have been asked during the week in the House of Commons on the proposed Marconi contract for the Imperial wireless telegraph scheme, in consequence of the announcement that communication over a distance of 3,600 geographical miles has been established by means of the Goldschmidt system.—The pending action by the Marconi Co. for alleged infringement of patents by the Helsby Wireless Telegraph Co. (Page 425.)

EDINBURGH cinematograph theatre proprietors are asking to be supplied with current at power rates.—Some definite progress now seems likely with the

Bethnal Green electric supply scheme.—In spite of the opposition of the Dublin Gas Co., an electric lighting Order has been granted to a private company for Kingstown.—Very satisfactory reports have been presented for the past year's working on the Sheffield, Wolverhampton, and Taunton electricity undertakings. (Page 427.)

A SWITCHBOARD panel and accessories is required at Christchurch (N.Z.); battery at Heywood; low-tension cables at West Hartlepool; converting plant, &c., at Todmorden; and an electric lighting scheme is to be undertaken at Waterford.—Extensions are contemplated at Shoreditch, St. Anne's-on-Sea, Stalybridge, Swansea, Loughborough, and Wallasey.—Trolley 'bus schemes are under consideration for Bloemfontein and Reading. (Page 427.)

At the General Electric Company's meeting last week Mr. H. Hirst, the Chairman, spoke of the very satisfactory result of the past year's working, in spite of the effect of the National Insurance tax, which amounts to from £3,000 to £4,000 per annum, and the coal and railway strikes. It is proposed to create a staff benevolent fund and possibly some superannuation scheme will be evolved. (Page 428.)

### THE "HALF-WATT" LAMP

**A**LTHOUGH it is likely that a metal filament lamp with an efficiency of about a half-watt per Hefner candle will be placed on the market in the autumn, it need not cause any unrest in the mind of the central station engineer who is anxious not to lose any of his lighting load, or of the contractor who will shortly be ordering his autumn stocks of lamps. The half-watt lamp, when it makes its first appearance, will certainly be no smaller than 1,000 c.p.; probably a start will be made by the A.E.G. Company with a 5,000 Hefner c.p. 2,500 watt lamp, suitable for 110 and 220 volts, and the 3,000, 2,000, and 1,000 c.p. sizes will follow later. The lamp has a drawn tungsten filament, which is subjected to a special treatment after drawing. The 5,000 c.p. lamp will doubtless compete strongly with are lamps for street lighting, and still more strongly for the lighting of large interiors, if the estimated life of from 1,000 to 1,500 hours is attained.

The Deutsche Gasglühlicht Aktiengesellschaft (the owners of the Osram lamp in Germany) are also developing a lamp on similar lines. This will also only be for very high candle powers at the outset—1,000 c.p. and more—and in this case possibly for voltages below standard.

It is seen that the announcements and comments that have been made in the Press with regard to the half-watt lamp—suggesting that the "half-watt" lamp will invade the market in its millions, and be taken up rapidly by contractors and the public, and that the central station engineer will have to seek consolation in the fact that there are other uses for electricity than for lighting—are all based on incomplete information. No panic is necessary, and the enthusiasm is premature; all that will happen in the immediate future is that arc lamp manufacturers will have to prepare for even more serious competition than hitherto from the metal filament lamp.

### ELECTRICAL TRADE WITH CANADA

**T**HOSE of our readers who are familiar with Canadian trade conditions are aware that the "National Electrical Code" of the rules and requirements of the National Board of Fire Underwriters, consisting of the British and American insurance companies, govern very closely the construction, component materials, and design of all such articles as switches, fuses, rubber-covered wire, flexible cord, conduits, flexible tubing, circuit breakers, lamp sockets, porcelain fittings, ceiling roses, motor starters and so forth, to be used in positions where a fire hazard is involved. The National Electrical

Code and the semi-annual "List of Electrical Fittings" issued by the Board of Fire Underwriters prescribe in the one case the general requirements to be met, and in the other case schedule of the approved fittings. The function of the Underwriters' Laboratories is to see that these rules and requirements are carried out. For this purpose it is necessary to submit samples of the apparatus to them for approval, after which inspections are made at regular intervals to ensure that the quality of the commercial article is maintained, and in certain specified cases supply labels which may be attached to them as evidence to the purchasing public that such have received their approval.

Hitherto all British-made electrical fittings of the above type for use in Canada have had to be examined by the Underwriters Laboratories' Inspectors after arrival. Arrangements have, however, now been made to enable this to be done in England. For this purpose, Messrs. A. C. Heap & W. Pollard Digby (48 Westminster Palace Gardens, Victoria Street, S.W.) have been appointed Engineers in Great Britain to the Underwriters Laboratories Inc., Chicago. They are prepared to make the necessary examination of goods before leaving the maker's factory, thereby giving to the British manufacturers the same facilities as those enjoyed by the American, and removing a difficulty to which his Majesty's Trade Commissioner in Canada has recently drawn attention.

Both partners have an intimate knowledge of British manufacturing conditions and apparatus, and Mr. Heap has paid several visits to Canada for the purpose of studying Canadian conditions and requirements. We are asked to intimate that Messrs. Heap & Digby will be pleased to give manufacturers any information they require as to the regulations of the Board of Fire Underwriters, and supply them with copies of the National Electrical Code.

### THE POST OFFICE TUBE RAILWAY

#### Opposition of Electric Lighting Companies

**T**HE proposal of the Postmaster-General to construct a tube railway from the east to west of London, linking up Mount Pleasant and the G.P.O. on the way, for the purpose of more expeditiously dealing with the mails, has been before a Committee of the House of Commons this week and last week. Although to the preamble of the Bill there is no real opposition, there are a considerable number of opponents who are seeking protective clauses, included among them being the London electric supply companies, who object to a power which, it is claimed, is taken under Clause 6 of the Bill, enabling the Postmaster-General to supply electrical energy in any part of London for post-office purposes.

The exact system to be adopted on the tube railway has not yet been definitely decided, but the tube will have a diameter of six feet, and some method of remote control is contemplated. It is estimated that 3,000,000 units per annum will be required, and this will be supplied from the existing Post Office power house at Blackfriars. Mr. W. Slingo, Engineer-in-Chief, in his evidence stated that the trains will consist of small trucks each carrying two motors capable of a maximum speed of 35 miles an hour. During the cross-examination of Mr. Slingo on behalf of the London electric supply companies, figures of the cost of generation at the Post Office power station were asked for, but were at first refused. Mr. Tyldesley Jones, who was cross-examining, asked for the ruling of the Committee upon the matter, and after consultation with his colleagues, the Chairman decided that these figures should be given. Mr. Slingo thereupon said that the cost of generation at Blackfriars, including capital charges, is 0.627d. per unit, and that the total cost delivered to either Mount Pleasant or King Edward Street would be 1.077d. per unit. This figure includes the cost of conversion to 440 volts, which is the voltage to be used on the railway, and will also be used on the three-wire system for lighting purposes at post offices if the Bill goes through as it is framed at present.

The electric supply companies' objection to Clause 6 is that it gives general powers to the Postmaster-General to compete with them in so far as Post Office property in any part of London is concerned. The complaint is made that the proposal is not confined even to lighting post offices on the line of the railway, but that the Clause as drafted enables streets to be broken up in any part of London. The electric supply companies have joined forces for the purposes of this opposition.

**A Floating Power House.**—The falls of the Ohio River at Louisville furnish perennial possibilities for the promoter, says the *Electrical World* (New York). The latest scheme contemplates a stationary barge or dock in mid-stream. Here energy is to be developed by turbines. The National Power Co. of Birmingham, Ala., is responsible for the scheme. A fifth of the authorised capital of a million dollars has been subscribed.

## THE EXHAUST STEAM GENERATING STATION AT WEST HARTLEPOOL

THE waste-heat generating station of the West Hartlepool Corporation is now completed, and about to take the whole of the load previously taken by the original station at Burn Road. Exhaust steam from the Seaton Carew Iron Company's blowing engines is supplied to two 1,250 k.v.a. 6,000-volt 3-phase 40-cycle improved Curtis two stage impulse reaction turbo-alternators in the new station, which is situated on land adjacent to the engine-house of the Iron Company. Should the low-pressure steam fail, high-pressure steam at 60 to 80 lbs. per sq. in. pressure can be obtained direct from the boilers and supplied to the turbines, which have a high-pressure stage for this emergency.

The original generating station at Burn Road will eventually become a substation, with some of the steam plant retained to deal with peak loads if necessary. The existing plant here consists of a miscellaneous assortment of small high-speed non-condensing sets of 1,500-kw. capacity, generating direct current at 460 volts, at which pressure a supply is given to various works, while domestic consumers in the town are supplied at 230 volts on the three-wire system. There is also a 460-volt 300-k.w. battery by the Tudor Accumulator Co., Ltd., and a steam balancer. This, together with a 600-kw. set and the battery, are to be retained and the smaller plant scrapped. The space so available will be occupied by Rosenberg self-starting rotary-converters, two of which are already installed, though only one is erected in its permanent position. As the battery is across the outers only, it is necessary to use balancers, and so a small booster capable of giving a 20-volt boost is erected on the shaft of each rotary. This machine may be connected between the third wire and either outer as required. The whole of the converting plant, including the transformers, was supplied by the British Westinghouse Electric and Manufacturing Co., Ltd. (Trafford Park, Manchester).

The station building is a steel skeleton structure with walls of concrete reinforced with expanded metal. It is 40 ft. high, 40 ft. wide, and 70 ft. long, and one end is of temporary construction so that the building can be readily extended to accommodate more plant, including the requisite steam raising equipment, if at any time the Iron Co. should cease its operations, so that continuity of the supply is assured. This was insisted on by the Local Government Board when the loan was sanctioned. The turbo-generators are situated on the upper floor of the power house and receive the exhaust steam from a 33-in. wrought-iron pipe fed from the exhaust of the Iron Co.'s blowing engines through a grease separator. In addition, a 10-in. pipe brings high-pressure steam from the Iron Co.'s boilers direct to the turbines. The boilers are fired by the waste gases from the blast furnaces. As there will therefore always be either a plentiful supply of exhaust steam or none at all, the turbines are arranged to work on either exhaust or high-pressure steam with the necessary governing, but the arrangements for changing over are not automatic. The usual trip gear to prevent the turbine running away is, of course, provided. The steam, after leaving the turbine, is condensed in a "contraflo" condenser installed on the ground floor of the station. Each condenser has 5,400 sq. ft. of cooling surface provided by 2,750 brass tubes  $\frac{3}{4}$  in. in diameter. The manufacturers of this apparatus are the Contraflo Condenser & Kinetic Air Pump Co., Ltd. (62 New Broad Street, E.C.). The condensed steam is pumped from the hot-well by a centrifugal pump back to the boiler-house of the Iron Co., and passes on its way through a Lea recorder. The cooling water is pumped from the Iron Co.'s deep well to tanks at the base of the three cooling towers, whence it is pumped through the condensers by 82-h.p. centrifugal pumps. Should this source fail, a supply of town water can be immediately obtained, as it is held in reserve. The condenser air pumps are of the "kinetic" type, and are each of 28 h.p. The cooling towers are of the Morrison cascade type, and are of very substantial construction. Each tower is divided into two parts and can easily deal with 115,000 gallons of water per hour, which is amply sufficient for one turbine. The contractors for the whole of the plant were Richardsons, Westgarth & Co., Ltd. (Hartlepool). The alternators were supplied by Siemens Bros. Dynamo Works,

Ltd. (Stafford), and have two poles. They are excited from a small machine on the end of the shaft at 100 volts through steel slip-rings. The efficiency of the alternators is about 93 per cent., and they are guaranteed to stand an overload of 25 per cent. for two-hours with only a 40° C. temperature rise. The stator terminals are conveniently arranged in a well at the bottom of the machine, which is ventilated by two fans on the rotor. These draw air in from the ground floor through a dry air filter supplied by the Sturtevant Engineering Co., Ltd. (147 Queen Victoria St., E.C.), along an inlet surrounding the shaft through the machine, and expel it out of a chimney at the top of the stator casing. Each alternator is provided with an earthing resistance and switch, so that only one need be used even when both machines are running. The main 6,000-volt switchboard consists of ten "fool-proof" ironclad panels of the well-known pedestal type, supplied by A. Reyrolle & Co., Ltd. (Hebburn-on-Tyne). A special panel and cable are set apart for the Seaton Carew Iron Co., Ltd. Current is conveyed to an oil-cooled transformer on the ground floor, where the pressure is stepped down to 440 volts. Thence it passes to a Rosenberg six-phase rotary-converter on the engine-room floor, so that a 230 and 460-volt D.C. supply is obtained. These rotary-converters are interesting as being among the first of the kind to be installed, and we understand the Westinghouse Co. guarantee to take them away and substitute the older type should they not give satisfaction. So far no tests have been made on the machines in the station, but we learnt from Mr. H. F. Friedrichs, who is the Borough Electrical Engineer, that the whole plant, including the rotaries, has been running, and the load taken by it very satisfactorily. The rotaries at the new station, and at the Burn Road station, which is now known as the Town substation, as well as one at a substation for supplying the South Durham Steel & Iron Co., are of 500-kw. capacity, giving 460/520 volts direct current when running at 600 r.p.m. They are wound six-phase and supplied from oil-cooled transformers stepping down from 6,000 volts, and are started by a small induction motor on the end of the shaft.

One is greatly impressed by the absence of the usual synchronising gear; in fact, the starting panel for each rotary contains only one instrument and a field discharge and reversing switch, which is only required if the machine should build up the wrong way—a contingency not likely to be realised, and low-pressure switches to short-circuit the starting motor when synchronism is reached, as indicated by a central zero voltmeter across the brushes of the converter, making a small oscillation from positive to negative for every slipping of one pole. Instead of labelling the various switches to show what circuits they control, they are numbered in the order in which the switchman has to attend to them, whereby there is no need for the switchman to have any technical knowledge at all.

The auxiliaries at the station are all driven by Siemens motors, and the various pumps are of the "Invincible" type, supplied by Gwynnes, Ltd., of Hammersmith. The pressure at which the motors work is 440 volts, obtained through an oil-cooled transformer, from which distribution is made by Reyrolle ironclad switchgear, using switch fuses of the type illustrated in *ELECTRICAL ENGINEERING*, Jan. 30th, p. 64. The equipment of the two turbo-alternators is exactly the same, and the auxiliaries can be connected through to either transformer by a link for the purpose. To start up the station two methods may be employed: (1) by running "back-over"; and (2) by closing all the switches to the auxiliaries in the station and admitting steam to the turbine. By this method a considerable time may elapse before the vacuum is picked up. The first method consists in starting up the rotary in the station from the D.C. side with current obtained from the Town substation, so that the auxiliaries may be supplied with power before the turbines are started up.

Besides the supply given to the Iron Co., two sets of cables connect the station with the Town substation, which is some 850 yards distant, one set direct, while the other supplies the South Durham Steel & Iron Co., through a looped-in substation on the way. The cables are mostly underground, but here they are taken overhead, as it was considered safer than to have them buried in the ground owing to the liability of heavy weights being dropped from the cranes in the yard. All the underground cables are paper insulated, lead covered

and armoured, and were supplied by Callender's Cable & Construction Co., Ltd. (Hamilton House, Victoria Embankment, E.C.)

It is intended ultimately to supply power to the tramways from the new station through the Town substation, but at present these are supplied from the generating station which belonged to the Company, which, until the recent purchase by the Corporation, worked them. The consulting engineers to the scheme were Messrs. Tennant & Barrs (Newcastle), with whom is associated Mr. J. F. C. Snell (Preece, Cardew & Snell, of Westminster). It may be remarked that the Borough of West Hartlepool may be divided into two portions, between which is the Town substation. One part is residential, and the other contains the ironworks, pit prop-sawing yards, and other works, as well as the suburb of Seaton Carew, where there is a considerable lighting load. Thus the old and new generating stations are favourably situated with regard to distribution, and now that cheap power is available in quantities no doubt additional works will be attracted to the vacant land near the docks and provided with railway siding accommodation.

One result of the division of the load thus has been that two sets of bus-bars are necessary, which are kept separate during the day; but at night, when the loads are more nearly equal, all the circuits may be taken from one set of bars. The load factor of the station for the twenty-four hours is about 27 per cent.

Our representative, who was kindly afforded facilities recently for inspecting the new plant, learnt from Mr. H. F. Friedrichs, under whose immediate supervision the plant was erected, that the Electricity Committee are about to embark on a campaign for the furtherance of electric cooking and heating, now that there is a margin of power available over the present demand.

### INTERCOMMUNICATION TELEPHONES

IN some types of intercommunication telephones it is necessary to perform several movements in order to effect a connection. This objection has been overcome in the new "Geeko" double-line intercommunication telephone, which

NEW G.E.C. INTERCOMMUNICATION  
TELEPHONE SET.

will shortly be placed on the market by the General Electric Co., Ltd. It requires only one operation for selecting and ringing. In other words, one button is pushed once only. Besides simplifying the operation of these telephones, improvements have been extended to their construction, so that they are free from "cross-talk," common with single-line telephones. The "Geeko" double-line auto-reset wall and table intercommunication telephones comprise a hand com-

bination fitted with Hunningscone-Deckert transmitter, equipped with an induction coil, circular bell, automatic cradle switch, especially designed combined line selecting and ringing auto-reset push buttons. All terminals are enclosed, and the external metal parts are nickel plated. The woodwork is of well-seasoned polished walnut. The table set is provided with cord and wall rosette. The wall type is shown in the illustration.

### INDIRECT LIGHTING FOR RESTAURANTS

INCREASING attention is being paid to providing lighting of a restful nature in restaurants, tea-rooms, &c., and an example of a recent installation where advantage has been taken of the good points of the indirect system of lighting is presented in the illustration reproduced here, which has been sent us by the British Thomson-Houston Co. The "eye-rest"

TEA-ROOM LIGHTED BY "EYE-REST" SYSTEM.

system, with its hidden reflector, which they have developed, has frequently been described in our columns, and is now extensively supplied to hotels, restaurants and tearooms. In the installation depicted, which is that of the tea-room of the new Empire Cinema, Newcastle-on-Tyne, the fittings were specially designed to harmonise with the style of the decorations.

### PUBLIC LIGHTING IN GARDENS

THE accompanying illustration portrays a night scene in the "Eden Gardens," Calcutta, which form the fashionable society rendezvous in the late afternoon and evenings. These gardens are under the control of the Public Works Department.

THE EDEN GARDENS, CALCUTTA.

For some time the illumination has been by means of arc lamps, but these have been recently replaced by 600-c.p. Osram lamps, fitted in cast-iron watertight fittings, on the existing arc-lamp poles. The improved illumination has been very favourably commented upon.

# IMPORTANT NOTICE TO THE PUBLIC.

## DRAWN TUNGSTEN FILAMENT LAMPS

**THE BRITISH THOMSON-HOUSTON  
COMPANY, LIMITED, OSRAM LAMP WORKS,  
LIMITED, and SIEMENS BROTHERS AND  
COMPANY, LIMITED,**

owners of Letters Patent relating to drawn wire tungsten filaments and lamps, beg to notify the trade and the public that the EDISON & SWAN UNITED ELECTRIC LIGHT COMPANY, LIMITED, have recognised the validity of the fundamental patent No. 21513/06 relating to such filaments owned by the British Thomson-Houston Company, Limited, and other Letters Patent of the British Thomson-Houston Company, Limited, Osram Lamp Works, Limited, and Siemens Brothers and Company, Limited, relating to drawn wire tungsten lamps, and have been granted a licence to manufacture and sell lamps under the said patents.

The Trade and the Public are hereby warned against selling or using infringing lamps. No possible risk or liability can be incurred by the Public in purchasing or using MAZDA, OSRAM or WOTAN LAMPS or lamps sold under licence from the undersigned.

## PUBLIC FIRE-ALARM SYSTEMS

**A** PAPER by Mr. E. E. Moore, describing the "Knight" open- and closed-circuit fire-alarm systems, has been accepted by the Institution of Electrical Engineers and published in the *Journal*. In this system the code signal is sent by a contact drum, revolved by clockwork, which is set in motion by a release cam, operated by the outward motion of the pull-handle, so that once the clockwork has started the operator has no further power over the instrument. When the code drum has made two complete revolutions it is stopped by the release cam re-engaging with the pull-handle trigger. Should another post be in operation provision is made for holding up a signal by means of an electromagnet and an extension circuit-breaking drum, on the same axle as the release cam. The holding-up arm operated by the armature of the electromagnet engages with a pin on the code contact-wheel directly the two contact-springs are earthed by the first metallic segment after the pull-handle has been operated. Unless the current then flows round the electromagnet coils and the armature is attracted, the clockwork is stopped. The circuit-breaking drum normally keeps two pairs of line-extension contact-springs respectively in contact; but when the clockwork starts revolving, and before the code contact-springs are earthed, the two pairs of line-extension contact-springs break contact. To indicate that the signal has reached the station there is an answering bell in the transmitting station which is rung by the return current. Telephonic communication is also provided. With one pattern a jack only is fixed. The action of plugging in a portable set causes the station to be rung by a continuous ring. With a fixed transmitter and receiver it is arranged that, after the code signal has been sent, the person giving the alarm can speak to the station by following simple instructions. On the mainspring drum is fitted a projecting cam which, when the clockwork has run for a few seconds, engages with the bolt that holds the door of the box fastened, and unlocks it. The door is then pushed open by means of a spring plunger and another instruction tablet is disclosed, which gives sufficient particulars to enable the operator to use the telephone, which is accessible only when the door is open. The spring is re-wound by the fireman who replaces the broken glass. On the pull-handle rod and at right angles to it is a projecting rod, while on the spring drum is a circular disc with a diametrical slot which only allows the pull-handle to go right home when the spring is fully wound. The winding lever is fitted with a ratchet movement. The spring drum, code drum, and extension circuit-breaking drum, being in solid mesh, will all revolve in a backward direction when the spring is wound up; and, if no provision were made, would then send an erratic signal to the station and drop a flap there. Although this would not be recognised as a regular intermittent signal and fire-alarm, the necessity for dropping a flap at all is obviated by arranging a circuit-breaking lever operated by a cam on the winding lever, so that during the short process of winding, the code contact-springs are lifted slightly off the drum, and the circuit cannot thus be put to earth through it. A non-inductive resistance of 3,000 ohms is provided and connected across the extension terminals of the end post on a circuit. The telephone gear at the post consists simply of a microphone and a receiver. The receiver normally hangs on an automatic switch hook.

Extensions can be made from the station, where a drop-flap annunciator is used, to the firemen's houses or to other places desired, or the circuits can easily be arranged through sub-stations.

In the open-circuit system, when a point is operated the clockwork rotates the code and circuit-breaking drums and disconnects both lines from all points farther away from the station than the point operated. The two code contact-springs are then earthed at the code drum, thus allowing current to flow from the station along both lines and through the electromagnet coils. The code drum continuing to rotate, the circuit to the station is thus intermittently earthed and broken.

The two lines become common after passing through test keys, the path of the current being through a circuit-changer operated by a drop-flap annunciator, through the annunciator electromagnet winding to the top contact of a control-relay armature, through the armature of this to the electromagnet of an alarm relay, and then through an earth indicator, battery,

and back to earth. Directly the armature flap drops, its electromagnet coil is cut out, the line current being switched on to another segment of the circuit-changer, and from thence in series through each of the other circuit-changers on the board to the telephone speaking-key, and then direct to the alarm relay. An ink recorder in shunt with the alarm bell automatically starts and stops itself. The annunciator therefore discloses the circuit on which the alarm has been given and the code gives the identical point.

Should two or more points on the circuit be operated at about the same time, all boxes farther away from the station are electrically cut off until connection is again made at the extension circuit-breaking drum, when the alarm at the post operated nearer to the station has finished its call. If a box, therefore, is operated whilst one nearer to the station on that circuit is operating, the clockwork is held up by the catch on the electromagnet, and no further manipulation of the pull-handle will affect this. The point to notice is that the clockwork is held up almost immediately after the handle has been pulled, and with the code contact-fingers earthing on the first metallic segment of the code drum. When the nearer box has finished its signal, and the extension lines are again joined up, current from the station energises the electromagnet and liberates the clockwork. The signal of the box that was held up will then automatically come into the station. If while a signal is being transmitted an alarm is sent from a box nearer the station the more distant box is cut off, its signal ceases, and the alarm from the nearest box comes into the station. But the code of the distant box, although interrupted, is not lost at the station. If the distant box is interrupted before the completion of its first code signal, then it is held up at the end of the first revolution of the code wheel; and when the lines are again joined through to it by the completion of the signals of a nearer box or boxes, then it automatically sends through and records its complete repeat intermittent and code signal. If, on the other hand, the box is interrupted after the completion of its first code, the clockwork runs down and the remainder of the signal does not come in. This is immaterial, as the first intermittent and code signal has already been received and recorded.

If two or more points on different circuits are operated at about the same time, provision is made for current from all other lines to be cut off and the signals held up as soon as the annunciator flap for the line in operation has dropped, but as soon as it is replaced the signals which were held up come into operation. With regard to faults, any likely fault, with the exception of a broken line not earthing, makes itself known at the station on the open-circuit system; and on the closed-circuit system all faults show their presence at the station. The method of joining up the alarm-boxes by loop-lines generally obviates the necessity of running the out-line on the same route as the in-line, so that there is little chance of their coming in contact; but even if this happens any point operated will ring into the station if the lines are otherwise in order and any other fault immediately proclaims itself.

**Electric Ship Propulsion for Canals and Rivers.**—Among the papers read at the recent summer meeting of the Institution of Naval Architects at Glasgow was one by Mr. J. Reid and Mr. H. A. Mavor, entitled "A Case for Electric Propulsion." The paper dealt with the conditions to be met in the lake, river, and canal traffic in Canada, and it was shown how the nature of the manoeuvring required, the type of ship used, and other conditions favoured the use of a compact prime mover, such as the Diesel engine, of fairly high speed, combined with a propeller running at a low but readily variable speed. These conditions offered a very advantageous field for electric transmission gear. After sketching the main features of the alternating-current system developed by Mr. Mavor, a description was given of the equipment of the *Tynemount*, a vessel under construction for this class of traffic. This vessel has already been described in *ELECTRICAL ENGINEERING*, September 12th, 1912, page 505, in connection with Mr. Mavor's paper before the British Association on the subject. On this ship, two 300 h.p. Diesel engines drive the two main alternators of 6 and 8 poles respectively, and the propeller is driven by a single 500 h.p. slow speed, squirrel-cage induction motor. Speed control is effected by alterations in the connections of the two stator windings of the motor, which give 30 and 40 poles respectively, and the two alternators. At full speed and power one winding is connected to each alternator, while the lowest speed is obtained by connecting the 40-pole winding to the 6-pole alternator. A single controller gives two speeds ahead and astern in this way. Mention was also made of the suitability of the system for the propulsion of dredgers and similar vessels.

## AN AUTOMATIC STAR-DELTA STARTER

A NEW self-operating star-delta starter for squirrel-cage induction motors has recently been developed by Switchgear & Cowans, Ltd. (Springfield Lane, Salford), and a number are in use in collieries. The starter is designed to meet the usual Home Office requirements both as regards factories and fiery mines, but it also possesses, in addition to the usual overload and no-volt trips, features which make it capable of protecting motors and plant against mishaps through handling by unskilled persons, and from damage by any but the most violent forms of mischief. For instance, to start a motor it is merely necessary to switch on by means of the handle (a feat requiring the minimum of discretion), all further

FIG. 1.—AUTOMATIC STAR-DELTA STARTER.

operations being left to the devices of the starter. The action of switching on closes the circuit and sets the change-over switch on "star" position (the laminated copper brushes and the "knife" type change-over switch, with their substantial auxiliary contacts, are clearly seen in the second illustration). When the motor has attained a predetermined speed, the switch automatically changes over from "star" to "delta," sufficient adjustment being provided to allow the change-over to be at normal working current or below it, or, as is sometimes necessary, above it. Switching off is either by hand, or, in the event of overload or loss of voltage, automatic. It is impossible to close the switch on a short circuit; moreover, if for any reason, such as an excessive starting load or a seized bearing, the motor fails to attain within an adjustable

FIG. 2.—STARTER WITH COVER REMOVED.

limited time the speed at which the change from "star" to "delta" is arranged to take place, the circuit is broken. This feature is obtained by an ingenious application to the overload trip of the well-known Statler time-lag, together with a simple magnetic arrangement by which the pull for a given current value, tending to operate the overload release in "star" position, is less than half the pull for the same current value, tending to operate the overload release in delta position, thus

providing perfect protection against overload both in "starting" and in "running." Incidentally all contacts are oil-immersed, and Messrs. Switchgear & Cowans, Ltd., supply the starter with or without cable boxes, or with inlets and outlets either screwed for conduit or merely bushed. The many advantages of such a starter are readily appreciated in places where unskilled handling may be the rule, and where rough and exacting conditions prevail.

## A WIRELESS RECEIVING APPARATUS FOR TIME SIGNALS

THE accompanying illustration shows the appearance of the new wireless receiving set, which, as we have already announced, the Synchronome Co. have placed on the market for the purpose of picking up the international wireless time signal, &c. Primarily designed for watch and clock-makers, the apparatus is appropriately called the "Horphone," and has been introduced at this date to enable them to take the time signals under the new international arrangements which were inaugurated on July 1st. In the centre is a large inductance with two sliders, which will enable stations of a long wave-length to be picked up on small aeri-als. A variable condenser is provided, also a blocking condenser, and a buzzer is fixed inside the case, with a press to operate it on the outside, for testing purposes. In addition to the necessary terminals, a plug is provided for the purpose of earthing the aerial during thunderstorms.

The crystal detector shown on the right is of a special design, and is claimed by the designers to be a great improvement on anything already on the market. The top and bottom castings give it a rigidity which prevents it easily getting out of the adjustment, as so many of the present detectors with spring construction are liable to do. Another important feature is the use of ball-and-socket joints, which enable any part of the crystal to be selected. The crystal itself is similar to silicon, but is more sensitive and reliable, and does not require a local battery; in fact, it has been found that applied E.M.F. renders it less sensitive. The crystal, &c., is enclosed in a glass cylinder, thus affording protection against dust, &c., and the whole detector can be taken to pieces in a few seconds by simply loosening the four clamping screws.

The apparatus is made in two different types, one comprising all the instruments mentioned above, while the more complete outfit, which has been selected for illustration, has in addition an electrolytic detector, potentiometer and dry cells, and change-over switch for selecting either detector. Double head-gear telephones of 2,000 ohms resistance are provided in either case. When not in use they are replaced on a hook, which in the larger set takes the form of a switch, thus when the telephones are replaced the local battery current through the detector is automatically switched off. If desired, a high-class chronograph watch is supplied with this set at an extra charge. The whole apparatus is very compactly and neatly mounted on a polished hardwood board, and, being listed at a moderate price, should appeal to those who are taking up the study of wireless telegraphy. A very simple form of aerial is sufficient, and the obtaining of the necessary license from the Post Office does not usually entail much trouble, as the set is used for receiving only.

THE HORPHONE.

# "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

## Specifications Published July 10th, 1913

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

13,997/12. **Dash-pots for Circuit Breakers, &c.** W. A. HARRIMAN and A. REYROLLE & Co. To overcome small obstructions, such as grit, a very thin flexible washer fits closely in the cylinder. The movement of the washer is limited by two discs or other means, and is also reinforced by them. One figure.

14,396/12. **"Thomas" Transmission System.** H. F. HAWORTH and THE THOMAS TRANSMISSION, LTD. To make possible the production of approximately steady pressure in spite of large current variations, two series machines mechanically coupled are used. The armature of one machine is in series with the fields of both, and this circuit is in parallel with the second armature. Thus, without special windings, the two series machines of the "Thomas" Transmission System may be temporarily converted into a serviceable generating set for regenerative purposes or electrical braking. Three figures.

14,576/12. **Ammeters and Voltmeters.** W. J. DAVIS and C. E. HUNTER (Ediswan Co.). Within a solenoid is a chamber of sector section with a vane constituting the moving iron pivoted along the apex. A fixed iron, with one end bent up round the edge of the moving vane when in the zero position, is also used. Five figures.

14,655/12. **Drawn Wire Lamps.** K. FARKAS. The filament is in two portions, each supported on insulated anchors interconnected within the lamp by a non-incandescing radial conductor passing diametrically through the stem. Four figures.

16,830/12. **Fault Clearing in A.C. Ring Main Systems.** A. M. TAYLOR. A star-connected primary and a delta-connected secondary on the consumers' pressure transformer are employed as well as a condenser. The secondary is also connected to the pressure coil of a wattmeter relay whose current coil is fed by transformers excited by the fault current in the line. This may be applied to systems of discriminating protection. One figure.

18,764/12. **Automobile Lighting and Ignition.** B. BROOKS and W. HOLZ. Within the interior of the poles of a lighting dynamo is a trembler ignition coil with its primary across the dynamo brushes, through a suitable switch. One figure.

24,343/12. **Dynamo Brushes.** W. E. LAKE (*Soc. Anon. le Carbone, France*). To improve the contact between brush and lead, a yoke or saddle piece is provided with corrugations or ribs near the angle formed by the end portions, and the central portion of the lead terminal in contact with the brush. Eight figures.

28,359/12. **Water Heater.** J. VON HENTZEL. The water is heated as it passes between two electrodes in a vessel which connects with the inlet and outlet pipes through insulating connections, and is surrounded by a non-conducting heat insulator. Four figures.

29,375/12. **Condenser Charging and Discharging for Wireless.** CIE. GÉNÉRALE RADIODÉGRAPHIQUE. Two groups of condensers are charged in parallel and discharged in series. After charging, one set is discharged for the time of a semi-oscillation and then discharged in series with the other group. This is effected by allowing the first set to discharge across a spark gap, or mercury vapour lamp, neither of which is in the series discharge circuit. Four figures.

3,525/13. **Boron-Tungsten Compound for Filaments.** F. HANSEN and W. F. MOHR. Tungstic trioxide is saturated with a solution of boric acid and then dried and heated in a neutral atmosphere. It is next mixed with zinc powder and reduced by heat, the zinc is removed by hydrochloric acid, and the residue thoroughly washed.

## Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** PORAK [Cable insulating and tensioning device] 16,671/12; SIEMENS-SCHUCKERT [Screw-propeller motor control] 2,136/13.

**Dynamos, Motors and Transformers:** B. T.-H. Co. (*G.E. Co., U.S.A.*) [Rectifiers] 18,747/12; B. T.-H. Co. and WHITAKER [Brush-raising gear] 25,704/12; KITSEE [Motors for driving kinematographs] 10,519/13.

**Heating and Cooking:** HARRISON [Ovens] 15,065/12.

**Ignition:** KETTERING, 12,047/12.

**Incandescent Lamps:** CLARKE [Lamps with filaments of the second class] 15,127/12; JULIUS PINTSCH [Filament supports] 15,485/12; BEUTELL [Mounting] 16,307/12; WESTINGHOUSE METALLFADEN GLÜHLAMPENFABRIK [Filament carriers] 26,288/12.

**Instruments and Meters:** EVERSHED & VIGNOLES and BINSTED [Recording] 17,226/12; B. T.-H. Co. (*G.E. Co., U.S.A.*) [Combined electric indicators and steam-flow meters] 22,262/12.

**Storage Batteries:** SOKAL, 15,404/12.

**Switchgear, Fuses and Fittings:** MAURICE and BYNG [Floor lamps] 17,247/12; WILKIE [Cable connectors] 18,060/12; LAMBERT [Combined switch and plug] 18,275/12; MARKS (*"Vulkan" Maschinen Fabriks*) [Switches for reversing electromagnetic clutches] 23,150/12; THOMPSON and BOWDEN [Time switches] 1,496/13.

**Telephony and Telegraphy:** AITKEN (*Automatic Elec. Co., U.S.A.*) [Telephone exchanges] 14,318/12; HILTZ [Printing telegraph receivers] 14,837/12; CLAUSEN [Call distributing] 14,945/12; KEITH [Telephony] 15,072/12; W.E. Co. (*W.E. Co., U.S.A.*) [Automatic exchange circuits and switches] 17,858/12; STERN [Telephone holders] 21,725/12; GRAHAM [Electromagnetic diaphragms] 4,197/13.

**Traction:** ANGUS [Railway signalling] 7,081/12, 6,330/13, and 6,652/13; SAMATA [Gear for actuating conduit covers and collector ploughs] 9,637/12; CHEATHAM [Point-operating mechanism] 14,739/12; ELEKTRO MOTOREN WERKE HERMANN GRADENWITZ [Aerial rail or rope ways] 15,920/12.

**Miscellaneous:** STERLING TELEPHONE Co. (*Schaffner & Co.*) [Mine exploders] 22,450/12; GASTOROWSKI [Electric sterilisation of closet seats] 26,485/12; MIRAM [Electromagnets to produce mechanical movements] 27,922/12; MACFARLANE [Solder for aluminium] 2,036/13; ERCOLE MARELLI & Co. [Oscillating fans] 6,496/13.

The following Specifications are open to Inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Distributing Systems, &c.:** HARTFORD [System for combined generation, storage, distribution, and utilisation of electric energy] 8,792/13.

**Electrometallurgy and Electrochemistry:** A.E.G. [Welding by means of increased resistance] 14,518/13.

**Incandescent Lamps:** A.E.G. [Lamp-making machines] 14,433/13.

**Switchgear, &c.:** JAKOBSEN [Combined switches and plug contacts] 14,330/13.

**Telephony and Telegraphy:** GIRARDEAU [Supply to antennae] 14,035/13; SOC. DE TÉLÉGRAPHES MULTIPLEX (SYSTEME E. MERCAIER, H. MAGUNNA) [Conversion of D.C. into isochronous undulating currents] 14,122/13.

**Miscellaneous:** DELAUNAY & BELLEVILLE [Temperature regulators] 9,269/13; [Self-propelling torpedoes] 9,271/13; FAUX [Three-phase differential gear] 13,450/13; CHERON [Illuminating apparatus or instruments] 13,822/13.

## Expiring and Expired Patents

The following Patents expire during the current week, after a life of fourteen years:—

14,703 of July 17th, 1899. **Flame Arc Electrodes.** H. BREMER. To prevent the accumulation of slag a boron or equivalent compound is used as an airtight coating. This melts at the arc and dissolves the slag, causing it to drop off.

14,704 of July 17th, 1899, by the same inventor. This specification covers the addition of 15 to 60 per cent. of a luminiferous metallic salt, and at least 5 per cent. of fluorine to the carbon. Compounds of boron, potassium, or sodium, may also be added. Another electrode described contains 10 to 60 per cent. of calcium fluoride.

The following are the more important Patents that have become void through non-payment of renewal fees.

**Arc Lamps:** CROMPTON & Co. and C. CROMPTON [Combined hand and electromagnetic control for arc lamps] 6,421/08.

**Distributing Systems, Cables and Wires, &c.:** V. P. VON PINDERSHOVEN [High pressure cables] 6,757/08.

**Dynamos, Motors, and Transformers:** V. A. FENN [Fynn single-phase commutator motors: divided field to effect reversal of rotation without brush shifting] 26,897/05; B.T.-H. Co. (*G.E. Co., U.S.A.*) [Slot wedges for induction motor stators] 7,048/07; H. F. BIGGE, F. R. BUTT, and J. H. WEBB [Transformers for electro-therapy, &c.] 19,885/08.

**Ignition:** F. R. SIMMS [Moving screen of Simms-Bosch magnet] 7,217/04; K. GLÖSSL and L. LITTMANN [Magneto armatures] 7,309/07.

**Incandescent Lamps:** A. G. BLOXAM (*J. Lux, Vienna*) [Tungsten filaments with 0.1 to 0.5 per cent. of aluminium and magnesium] 7,188/06; [Squirited metallic filaments with oxide or sulphide of cadmium or zinc] 7,189/06.

**Traction:** W. P. THOMPSON (*C. T. M. V. de Bangor, France*) [Wheel arrangements for rolling stock] 6,715/03.

**Miscellaneous:** J. A. LIDDLE [Capstans and winches] 6,493/08; J. FOLEY [Fire alarm and extinguisher] 6,577/08.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,347.

In a 2,000-volt A.C. generating station of 3,000-kw. plant capacity (2 units of 1,000 kw., 1 unit of 500 kw., and 2 units of 250 kw.), a 1,000-kw. set and a 500-kw. set are running at nearly full load about 2 hours before peak time. The peak load expected is 2,500 kw. The ammeters on one of the feeder panels and on the panel of the 1,000-kw. set suddenly go hard over, and the switches on these two panels trip. State, in chronological sequence, what you would do if you were in charge at the time.

(Replies must be received not later than first post, July 25th.)

## AN EXHIBITION TELEPHONE EXCHANGE BOARD

ONE of the most interesting stands from an electrical point of view in the British section of the Ghent Exhibition is that of the General Post Office occupying the whole of one court, where nearly all the apparatus is shown in actual operation. Of special interest is the model of a central battery telephone exchange equipment, as manufactured by the Western Electric Co., Ltd. (North Woolwich), arranged so as to show the various movements involved in connecting one telephone subscriber to another through a telephone exchange. The subscribers' switchboard, trunk switchboard, distributing frames, and coil racks are all shown

WESTERN ELECTRIC SWITCHBOARDS AT THE GHENT EXHIBITION.

in a truncated or modified form, with the wiring of the exchange equipments and the subscribers' telephones open to view, so that the whole sequence of operations may be followed with ease. A standard ringing dynamotor with inter-ringer attachment provides the ordinary ringing current, and the engaged and no-answer signals for the model. A battery

of portable accumulators by the Chloride Electrical Storage Co., Ltd., furnishes current for the speaking circuits and switchboard lamp signalling. It is seldom that the opportunity is given to follow the working of a modern telephone exchange in a way that will be so readily comprehended.

## INDUSTRIAL LIGHTING INSTALLATIONS

OUR attention has been called to some examples of lighting of industrial premises recently carried out from designs by the British Thomson-Houston Co., Ltd. (Mazda House, Upper Thames Street, E.C.). In these their metal "Mazdalux" reflector is used, which not only gives good efficiency in useful illumination, but at the same time serves to cover the lamps, so that the eyes of the workers shall not be dazzled and irritated by the glare of the incandescent filaments. These reflectors are made in four vertical types, giving respectively extra extensive, extensive, intensive, and focussing distributions of light, and in four angle types, giving maximum light intensity at 15°, 30°, 45°, and 90° from the vertical. Mazdalux reflectors have an aluminium reflecting surface, and the angle types are made entirely of aluminium, the others being supplied in steel or aluminium, as desired. The exterior surface is covered with a durable rust-proof

THE WESTMINSTER GARAGE, SHOWING ARRANGEMENT OF LIGHTING.

enamel. One of the installations in question is at Messrs. J. Ore & Sons, Textile Mills, Castleton, where the Mazda lamps are all suspended at such a height as to be outside the normal range of vision of the operatives. Another example is the Westminster garage. The problem in a motor garage is to get a uniformly distributed illumination of moderate intensity without dark shadows. With cars standing about in various positions, the last condition can only be fulfilled by suspending the light units at a considerable height, so that deep shadows are not cast. In this case these requirements are met by the use of Mazdalux reflectors and high candle-power Mazda lamps hung close to the ceiling. The ceiling lights are supplemented by a row of angle Mazdalux reflectors along each side wall.

**The Association of Consulting Engineers.**—Mr. G. Midgley Taylor presided over the Annual General Meeting of this Association at the Institution of Electrical Engineers on Monday, June 30th, when Prof. D. Capper, Mr. E. M. Eaton, Mr. R. Hammond, Mr. A. J. Martin, Mr. H. S. Childe, and Mr. W. L. Spence were elected to the Committee in place of Messrs. Douglas Latham, Mansergh, Stevenson, Harrison, and Miller, who had been drawn by ballot to retire in accordance with the rules. The Chairman referred to the meeting of foreign associations of consulting engineers, to be held in Ghent, July 17th to 22nd, which would probably be attended by their Treasurer, Mr. Lowcock. The report was adopted and auditors were appointed, and an amendment to the rules was carried (subject to confirmation at a special meeting) extending the qualification to members of the Institution of Civil Engineers of Ireland. It will be remembered that at present only corporate members of the Institution of Civil Engineers and full members of the Institution of Electrical Engineers are admitted.

## CATALOGUES, PAMPHLETS, &amp;c., RECEIVED

**VACUUM CLEANERS.**—A leaflet from the General Electric Co., Ltd. (67 Queen Victoria Street, E.C.), describes the "Santo" electric vacuum cleaner, which is a very conveniently arranged set in a cylindrical case on ball castors, not too heavy to be carried by one person. The pump is of the diaphragm pattern, giving a much more powerful vacuum than the centrifugal fans used on the smaller machines. A particularly complete equipment of accessories is supplied. A smaller set of the self-contained type is also listed for those requiring a cheaper outfit.

**POCKET LAMPS.**—Another new leaflet from the General Electric Co. introduces us to an attractive pocket electric flash lamp resembling a magazine pistol in appearance.

**FLAT TUMBLER SWITCHES.**—The "Imp" single- and two-way tumbler switches are some of the latest products of A. P. Lundberg and Sons (477 to 489 Liverpool Road, N.). From the illustrations of the "Imp" flat switch with plain brass cover, here reproduced, it may be seen that the switch is

strongly constructed and efficiently insulated. The main features of the well-known "Pivot" movement have been retained, while the depth of switch is very little, and it is also adaptable and convenient for flush work. The covers for these switches are obtainable in a large number of handsome designs.

**INSULATING VARNISHES.**—A leaflet from Chas. H. Blume (Insulating Varnish Department, The White Building, Fitzalan Square, Sheffield) gives particulars of the various grades of "Megomac" and "Insulac" insulating varnishes which are manufactured by this firm.

*Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."*

**THE DESIGN OF POLE LINES.**—We have received from Richard Wade, Sons & Co., Ltd. (Hull) a copy of a revised edition of their useful booklet of tables, giving particulars of wooden poles and data required for the design of overhead lines. These are very complete and well arranged. The revision of the tables has been rendered necessary by the Board of Trade having reduced the wind pressure for which wires and poles for E.H.T. lines have to be calculated from 30 to 25 lbs. per sq. in. The firm are sending copies to their regular customers, and any who have not received one are requested to communicate with the firm. Others can obtain a copy of "Wade's Tables" for 2s. 6d.

**MERCURY VAPOUR LAMPS FOR BLUE PRINTING.**—A compact piece of apparatus for producing blue prints from a continuous roll of printing paper by the light of mercury vapour lamps is described in a leaflet from the Westinghouse Cooper Hewitt Co., Ltd. (80 York Road, King's Cross). The paper and tracings travel continually at a speed of from 2 ft. to 4 ft. per minute over a glass cylinder, within which are two horizontal tube mercury vapour lamps. The feed rollers are electrically driven, and the whole apparatus is self-contained.

**HEATING AND COOKING APPARATUS.**—An illustrated catalogue and price-list from Credenda Conduits Co., Ltd. (Chester Street, Aston, Birmingham), deals with a very complete range of kettles, milk warmers, hot plates with special steel utensils for use thereon, boiling pots, irons, &c., and a new pattern of moderate-sized oven.

**SWITCH AND DISTRIBUTION BOARDS.**—The Emanda Engineering Co. (Emanda Works, Summer Avenue, Peckham, S.E.), who are specialists in distribution boards, accumulator switchboards, &c., have sent us a large illustrated sheet showing several patterns of these, accompanied by one of the neat little boxes of cigarettes which they are distributing to bring their name before the public.

**ENGINE-ROOM TELEGRAPHS.**—The Calten system of electrical engine-room telegraphs, which is extensively used in Dutch and other ships, is described in a pamphlet from Hogan and Wardrop (2 Gresham Buildings, Basinghall Street, E.C.).

## ELECTRIC TRACTION NOTES

The new railway that is to be constructed in Switzerland from Sierre (Valais) to Goppenstein, linking up the former town direct with Berne via the Loetschberg tunnel, will be run electrically on the single-phase system by locomotives. This railway will be a main line of standard gauge, 25 km. in length, and will involve six tunnels, two large viaducts, and four intermediate stations. The ruling gradient will be 2.75 per cent., and the total rise from Sierre in the Rhone Valley to Goppenstein in the Loetschenthal is about 2,250 ft.

Siemens Bros. Dynamo Works have been awarded the contract for rotary converters for the twelve substations of the Melbourne suburban railway system; the total capacity is 40,000 kw. It includes fourteen six-phase rotaries of 2,000 kw., 1,500 volt D.C., 25 cycle, 250 r.p.m.; ten rotaries of 1,000 kw., 500 r.p.m., and four rotaries of 500 kw. at 750 r.p.m. The rotaries must be capable of carrying these loads for twenty hours continuously, and of taking overloads of 3000 kw., 1,500 kw., and 750 kw. respectively after a twelve hours' run at rated load, without overheating. Finally, they must stand overloads of 4,000 kw., 2,000 kw., and 1,000 kw. respectively for ten minutes, and 6,000 kw., 3,000 kw., and 1,500 kw. momentary overloads. The static transformers will be supplied by the same firm, and will be oil-cooled with external oil circulation, and will be designed with large internal reactance in view of the wide regulation required for the rotaries. The direct-current voltage of 1,500 volts will be obtained off one commutator. Starting up will be accomplished on the three-phase side by means of an asynchronous starting motor.

The Sheffield tramway accounts record an increase in the traffic receipts of £21,137, bringing the total income up to £362,127. The balance on the year's working is £77,296. After apportioning £7,631 to street improvement and meeting renewal and other special charges, £30,234 was contributed to the rates.

The Board of Trade report of Major Pringle on the derailment of a portion of an electric train on the Metropolitan District Railway near Sloane Square station on April 26th has been issued. The train came to a stand owing to the current being cut off, and it was found that the back portion had left the rails owing to the leading axle of a trailing car having broken near its centre. The inspector attributes the fracture to an internal flaw such as could not have been detected by the ordinary methods of examination. Damage was done to the track, and a short circuit was caused, which blew out the circuit-breaker and cut the current off. The adjoining down road was not fouled, but the short circuit caused its signal to go to danger.

Mr. T. B. Goodyer (Tramways Manager, Croydon) has addressed a circular letter to a large number of Members of Parliament urging the necessity of legislation to place the Motor Omnibus Companies on terms of equality with regard to public obligations with the Municipal Tramway authorities in the Metropolitan area, and pointing out how seriously the matter affects the ratepayers.

We refer in another column to the Post Office tube railway which is now under consideration by a House of Commons Committee.

The bill of the City & South London Railway Co., which provides for its reconstruction in order to admit of rolling-stock from the other tube railways, has been passed by a House of Commons Committee. It has already passed the House of Lords.

The proposal of the Metropolitan Railway Co. to take over the Great Northern & City Tube Railway, which has already passed the House of Lords, has now passed the House of Commons.

The scheme of the Metropolitan Electric Tramways, Ltd., to run a service of trolley-buses from Wood Green to the boundary of Walthamstow has now been passed by both Houses of Parliament.

The revenue of the Glasgow Corporation Tramways for the year to May 31st exceeded for the first time in the history of the undertaking £1,000,000, the exact figure being £1,007,652. There is a net balance of £33,000 after setting aside £130,000 for depreciation and £85,000 for permanent-way renewals.

The House of Commons has rejected a clause inserted in the L.C.C. Tramways Bill by a committee, giving the London United Tramways Co. compulsory running powers over the Company's lines in London which have recently been purchased by the Council.

## TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

The Canadian Government proposes to erect a wireless station on Mount Royal, Montreal, requiring land 800 ft. by 200 ft. According to the *Electrical News* (Toronto) the antenna will be supported on two wooden masts 180 ft. high and 450 ft. apart. The size of the operator's building will be 40 ft. by 20 ft. The station will be capable of communication with the Quebec station to the east and the Kingston, Ontario, station to the west, thus linking up the Government wireless stations on the Great Lakes with that on the east coast, and completing a chain of stations which will extend from Port Arthur, at the head of the lakes, to Cape Race and Belle Isle on the Atlantic. There is at present a station in Montreal, but it has a very limited range which cannot be increased owing to the position of the site. The National Battlefields' Commission have given the Government leave to erect a station on the battlefield at Quebec.

The Norwegian Government has sanctioned an agreement with Marconi's Wireless Telegraph Company for the establishment of a wireless service between Norway and America. According to a Reuter telegram, a sum of £111,100 has been voted for the construction of a wireless station near Stavanger. The American station will be situated in Massachusetts or Connecticut and divided into two parts for transmitting and receiving some twenty miles apart. These stations will form part of a world chain, which includes the stations at San Francisco, Honolulu, Yokohama, Bangalore, and Alexandria.

The announcement that wireless telegraphic communication has been established by means of the Goldschmidt system between Hanover, in Germany, and Tuckerton, near Atlantic City, a distance of 3,600 geographical miles, gave rise to a number of questions during the past week in the House of Commons bearing on the proposed Marconi contract for the Imperial Wireless Chain. The Postmaster-General, in reply, said that he had asked the company to allow demonstrations to be witnessed by the officers of the Post Office and the Admiralty, but the company stated that they were not in a position to give any demonstration until the first week in August. If the suggestion which had been made to invite tenders for the Imperial Wireless Chain, based on a guaranteed minimum standard of efficiency laid down by the Post Office and approved by the House of Commons, were adopted it would involve a delay of nine months or a year before work on the stations was begun. He was, however, he said, pointing out to the company that under certain conditions the erection of the second three stations of the chain would be transferred from the original contractors to others whose system might be proved more efficient or economical. With regard to Dr. Austin's report on the recent tests of the Poulsen system between Arlington and Gibraltar and the U.S. ship *Salem*, as a result of which it was said that the American Poulsen Company were awarded the contract for the Panama station, which was to have a range of 3,000 miles, he said that he had asked for a copy of the report, which, he believed, had not been published, but had not received one. He would not publish the correspondence between himself and the Postmaster-General of Canada relative to the agreement for the Transatlantic service between this country and Canada on the Poulsen system, as the agreements were wholly different in character. He had been asked last Saturday by the Universal Radio Syndicate, Ltd., for permission to be allowed to tender for the Poulsen system. There were a number of companies who wished to tender and who would give guarantees, but he wanted no guarantees, but stations which would work. Asked as to the nature of the agreement entered into between the Norwegian Government and the Marconi Company for the North Europe Transatlantic service, he said that the American Marconi Company

was a party to this agreement and undertook to erect in the United States a station similar to the one provided in Norway by the British Marconi Company. This was to be similar to those in the British Imperial Chain, but the purchase price was to be £70,000 for the one station, and the Norwegian Government had the option of commuting the royalty payments for a lump sum of £80,000 at any time. Under the contract with the British Government no work of any kind would be carried out by the American or Canadian Companies.

Mr. Justice Eve had before him last week an adjourned summons in the pending action between the Marconi Co. and the Helsby Wireless Telegraph Co., mentioned in our issue of April 10th, p. 207. The present hearing resulted from an order in chambers giving the Marconi Co. power to ask certain questions relating to the wireless system of the Helsby Co., after an inspection last May. The Helsby Co. argued that some of the questions asked would, if answered, disclose information of their apparatus prejudicial to the trial. It was held, however, that the Marconi Co. could ask that in the event of any apparatus shown to the Marconi Co. not being an infringement of the Marconi patents, what alterations had been made between the issue of the writ for infringement and the inspection. The case itself, which is an action alleging infringement of the famous Marconi patent 7777/1900, will probably come on for hearing to-day or to-morrow.

It is of some interest in connection with the recent agitation for additional telegraphic facilities to the north of Scotland that the Postmaster-General is said to be arranging for the erection of a wireless telegraph station near Stonehaven, a few miles south of Aberdeen.

It was stated in the House of Commons by Mr. Harcourt that a 5-kw. wireless station employing a French system is now being erected in the Bahamas, and contracts are being entered into for the erection of similar stations at Barbados, Mombasa, Singapore, Penang, and Hongkong. The Postmaster-General also stated, in reply to a question, that the erection of the emergency wireless station for St. Kilda would shortly be complete. It was a private undertaking erected under licence granted in January, and would communicate with Loch Boisdale at a charge of 3d. per word, with a minimum of 6d. per message.

A new wireless station, with a range of 200 miles by day and up to about 1,000 by night, has recently been opened at Balboa for ship-to-shore work on the Pacific side of the Isthmus of Panama. According to the *Electrical Review and Western Electrician* (Chicago), the plant is only of 2-kw. capacity, arranged on the "break" system, which allows a receiving station to break in on the transmission of a message, in order to ask for repetition or explanation. In the intervals when the sending key is released between dots and dashes it opens a relay in the receiving circuit, and the operator is able to hear calls from other stations. The antenna is horizontal, and about 110 ft. from the ground.

As already stated in these columns, telephonic communication will shortly be established by the American Telephone & Telegraph Co. between New York, Los Angeles, and San Francisco, over a distance exceeding 3,500 miles. According to the *Elektrotechnische Zeitschrift*, the conductor will be a copper wire 4.5 mm. in diameter, and Pupin coils will be installed every 8½ miles. On account of the difference in time between New York and San Francisco, the line will only be in use for a few hours out of the twenty-four, and consequently a very high tariff will be applied. The charge for a three-minute conversation will be between £3 and £4.

The Roumanian Administration wish it to be known that the prohibition regarding the use of secret language does not apply to telegrams other than those destined for their country, which means that telegrams in transit may be still sent in code.—Communication is down to the States of Morelos Durango and Coahuila in Mexico.

## LOCAL NOTES

**Blackburn:** *Electric Car.*—Following the example of many other central station engineers, Mr. P. P. Wheelwright has now in use in the service of the Electricity Department an electric car fitted with an Edison battery.

**Edinburgh:** *Supply to Cinematograph Theatres.*—The Electric Lighting Committee last week received a deputation from cinematograph theatre owners on the question of the rates charged for electric current for projector purposes in cinematograph theatres. The request was that all current supplied for this purpose, especially where motor-generators are installed, should be charged for at power rates instead of lighting rates as at present. It was claimed that this concession has been granted in other towns in Scotland, including Glasgow. The Convener of the Committee promised to give the subject favourable consideration in view of the importance which this industry is assuming.

**Hull:** *Electricity Accounts.*—There was a net profit of £7,725 upon the electricity undertaking last year, which is an increase of £1,254 over that of the preceding twelve months. The City Electrical Engineer's report states that the motor-hiring scheme initiated in 1905 shows a steady increase, the total number of motors now out on hire being 203, representing a total horse power of 1,170. Mr. H. Bell, the City Electrical Engineer, has been congratulated by the Electricity Committee upon the results, especially having in mind the largely increased cost of coal during the past two years.

**Kingstown:** *Electric Lighting.*—The Dublin Southern District Electric Supply Co., Ltd., were successful before a House of Lords Committee last week in getting passed the preamble of their Bill providing for the electric lighting of Kingstown. There was considerable opposition from the Alliance and Dublin Consumers' Gas Co., who, it was stated, intend to apply to the Board of Trade for an order to supply electricity in all three neighbouring districts, Kingstown, Dalkey and Blackrock.

**London:** *Bethnal Green: Electricity Supply.*—The scheme for the supply of electrical energy in bulk by the Stepney Council is now taking a more definite shape, and the matter is being expedited in consequence of applications from possible consumers.

**Hammersmith.**—Mr. G. G. Bell (Borough Electrical Engineer) has devised a scheme for transporting coal from barges at the nearest wharf on the Thames direct to the electricity works, a distance of some 600 yards. The idea is to have a large tank at the wharf and one at the electricity works, connected by two pipes. A circulation of water would be maintained by powerful pumps sufficient to carry the coal from the first tank, into which it is dropped by grabs, to the tank at the station, whence it is removed again by grabs.

**Macclesfield:** *Electric Supply.*—The new Electricity Company of Macclesfield is now getting to work. A site has been obtained for a power station in which it is intended to instal Diesel-engine plant.

**Sheffield:** *Electricity Accounts.*—The total number of units sold last year was 21,671,978, against 16,902,360 in the preceding twelve months, the total connections having grown from 30,088 kw. to 33,835 kw. The working costs were 0.44d. per unit, against 0.52d. in the previous year. The net surplus was £11,515, which is increased to £18,490 by the balance brought forward. A further sum of £10,000 has been transferred to renewals account. The wiring and fittings department shows a net profit of £1,988, after meeting interest and working fund charges. The electricity department has been debited with £1,878 special law charges for the year.

**Stalybridge:** *Electricity Accounts.*—The accounts of the electricity undertaking of the Stalybridge, Hyde, Mossley, and Dukinfield Joint Tramways and Electricity Board show a loss for last year of £9,124, which has to be met equally by the four authorities concerned.

**Taunton:** *Electricity Accounts.*—The result of the past year's trading of the Municipal Electricity undertaking was a gross profit of £5,044. The whole of this is exhausted in meeting expenditure of a capital nature, transferring to renewals fund in respect of switchboard, machinery, mains and meters. £212, and transferring to free wiring purchase account £1,067 10s. This latter is in settlement of all claims of the National Electric Construction Co. in respect of free wired installations, and in order to pay the whole account off in one instalment. £510 has had to be withdrawn from the

reserve fund. Had it not been for this charge on the undertaking for the year, there would have been a net profit of £558.

**Wolverhampton:** *Electricity Accounts.*—The profits on the electricity undertaking for last year constitute a record, and the sum of £2,125 has been transferred to relief of rates. With the amount now added to reserve fund, the latter stands at £15,356.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

## Generating Stations, Sub-Stations, Mains, &amp;c.

**Christchurch (N.Z.).**—Thirteen panel E.H.T. switchboard and accessories for the Lake Coleridge scheme. Further particulars at 73 Basinghall Street, E.C.

**Heywood.**—A new battery is required for the Corporation.

**Kettering.**—Sanction has been received to a loan of £1,400 for cable.

**London:** *Shoreditch.*—An expenditure amounting to £98,850 is recommended in connection with extensions at the Whiston Street power station.

**Loughborough.**—The Council has sanctioned applications being made for loans of £11,000 for machinery, and £3,000 for cables, meters, &c. It is proposed to instal a 1,000-kw. turbo-alternator.

**St. Anne's.**—An inquiry was held last week concerning a loan of £3,000 for mains and services.

**Stalybridge, &c.**—A proposed loan of £22,550 for the Joint Tramways and Electricity Board was inquired into last week. The Hyde Property Owners Association opposed.

**Swansea.**—An inquiry concerning a loan of £40,000 for extensions at the electricity works was held last week.

**Todmorden.**—Converting plant, H.T. switchboards and cables, mechanical stokers, superheaters. Borough Electrical Engineer, July 26th.

**Wallasey.**—An inquiry was held last week concerning a loan of £13,500 for electrical extensions.

**Waterford.**—On the advice of Mr. Mark Ruddle, Chief Electrical Engineer to the Dublin Corporation, the Council has definitely decided to promote a municipal electric lighting scheme.

**West Hartlepool.**—Low-tension cables, also pilot and telephone cables. General Manager, July 21st.

## Wiring

*The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.*

**Alloa.**—Tenders are required for the electrical work in a new picture palace at 62 Mill Street. Architect, J. D. Swanston, Kirkealdy.

**Barnsley.**—Variety theatre. P. A. Hinchliffe, 14 Regent Street.

**Blackburn.**—New fire station.

**Derby.**—Secondary school. Education Committee.

**Edinburgh.**—Barracks. Director of Army Contracts, War Office, S.W.

**Greenock.**—New school. Clerk, School Board.

**Hereford.**—Secondary school. County Surveyor.

**Lincoln.**—Nurses' home and additional ward at County Hospital. Architect, W. G. Watkins, St. Edmonds Chambers, Silver Street.

**London:** *Bermondsey.*—Re-wiring of Infirmary, Lower Road, Rotherhithe. Architect, A. H. Newman.

**Paddington.**—Public baths. (£40,000.)

**Middleton.**—New town hall.

**Newcastle-on-Tyne.**—New elementary school. Architects, Harrison & Ash, Education Offices.

**Redditch.**—Shops in George Street.

**Seaton-Carew.**—New school.

**Sunderland.**—Proposed training college. (£15,000.)

**Walsall.**—New baths.

FOR  
STEAM JOINTS  
USE

JOHN HUDSON & CO.'S SUCCESSORS, Mansell St., London, E.

## Miscellaneous

**Bloemfontein.**—A complete installation of trolley vehicles including power plant is required. (See advertisement on another page.)

**Reading.**—A trolley-bus scheme at an estimated cost of £23,839 has been prepared by the Tramway Manager.

**South Africa.**—Three electric bed lifts are required for the new hospital at Port Elizabeth. Further particulars, 73 Basinghall Street, E.C.

## TENDERS RECEIVED AND ACCEPTED

**South Shields.**—Contracts have been placed with Siemens Bros. Dynamo Works for twelve months' supplies of "Wotan" lamps for car-shed and office lighting, and "Tantalum" traction lamps for trams.

**Sunderland.**—The following tenders have been accepted:—Oil switches and meters, Ferranti, Ltd.; L.T. cable, British Insulated & Helsby Cables; winding motor-generator, Phoenix Dynamo Co.

## APPOINTMENTS AND PERSONAL NOTES

Mr. W. J. H. Wood, at present Station Engineer at Bolton, has been appointed Chief Electrical Engineer in succession to Mr. A. A. Day, who was recently compelled to resign through ill-health.

A tramways manager is required by the Southampton Corporation. As we recently announced, Mr. H. F. Street, who has hitherto held the dual position of Borough Electrical Engineer and Tramways Manager, found the development of the electrical undertaking sufficiently rapid to occupy the whole of his attention.

The scheme recently mentioned in this column for the payment to Mr. W. A. Vignoles, Borough Electrical Engineer at Grimsby, of a commission of 5 per cent. on the net profits on the electrical undertaking, above the sum of £2,500 per annum, in addition to his salary of £550, has now passed the Grimsby Council.

## MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. George Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £65 to £65 15s. (Last week, £67 10s. to £68.)

**Books.**—Messrs. W. & G. Foyle, the well-known second-hand booksellers, inform us that they have opened a foreign book department at 5 Manette Street, adjacent to their premises in Charing Cross Road.

**Annual Outings.**—The office and works staff of the Linolite Co. (25 Victoria Street, S.W.) held their annual outing at Herne Bay on Saturday, 5th inst.

The Annual Outing of the White Electrical Instrument Co. (2 and 4 Gloucester Street, Camberwell) took place on Saturday last, and a most enjoyable day was spent at Burnham-on-Crouch.

**Works Holiday.**—Mawdsley's Ltd. (Zone Works, Dursley, Glos.), inform us that their works will be closed from August 1st to 11th, and that only urgent correspondence will be dealt with during this period.

A. P. Lundberg & Sons (477 to 489 Liverpool Road, N.) will be closing their works from August 2nd to 11th, when only urgent correspondence can be dealt with and goods which happen to be in stock despatched.

**Agency.**—Morris & Lister, Ltd. (Carlton Works, Lockhurst Lane, Coventry), in order to deal with the increased demand for their time element circuit breakers and transformers and other manufacturers, have placed their representation in the hands of Morris & Lister (London), Ltd. (3 and 4 Palace Chambers, Westminster; Tel.: Ken. 5164).

**Exhibition Award.**—Ferranti, Ltd., have been awarded a gold medal diploma for the switchboard which they are exhibiting at the Ghent Exhibition.

## COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &amp;c.

**General Electric Co.**—At the ordinary general meeting held on Thursday last week the Chairman, Mr. Hugo Hirst, said that the company was once more in the fortunate position of being able to place before its shareholders a report which showed satisfactory progress. Besides putting aside £30,000 to reserve, they proposed to create a new kind of reserve under the heading of "Staff Benevolence," for which they put aside conditionally this year £3,000. They proposed to study, within the next few years, whether something in the way of a contributory superannuation fund might not be started, and if found possible they wished to send it into existence with a sound start-off. They thought it only proper to provide a fund so that they would not be found unprepared and not be influenced in their grants during possible periods of depression. Now that loose plant, tools, patterns, and sundry utensils were written down to £1, fixtures and installations to £1, goodwill and patents to £1, freehold land and buildings £193,755 10s., fixed plant and machinery to £76,500, while by a recent valuation the last two figures had been shown to be over £100,000 less than actual value, they felt justified in returning to the dividend enjoyed before the big manufacturing enterprises were started. The item on the balance sheet appearing as "Investment" might be divided under four headings: (1) Investments in Sundry Works.—This referred to certain manufacturing departments producing specialities—especially telephones, conduits, and lamps—turned, for purposes of policy, into separate companies, entirely under the control of the General Electric Co. The company's investments under this head amounted to approximately £100,000. (2) Trading Companies Abroad.—These were the General Electric Companies of South Africa, Australia, India, China, Argentine, France, Spain, and Belgium. Some of these had started contributing towards the dividend, others still had very considerable establishment charges to their debit. The money invested in these companies was about £160,000. (3) Electrical Supply Companies.—Most of these were either under the control of the company or managed by it. They included the following undertakings: Madeira, Uitenhage, Bogota, Frinton, Barbadoes, and Macclesfield. A number of these undertakings were already paying satisfactory dividends. (4) Sundry Investments.—Some £10,000 or £12,000 represented small ventures found desirable in the course of trading, but whether they were dividend-earning or not, they all contributed in a lesser or greater degree towards the increased trading profits. The company had had to bear the first blunt of the National Insurance Tax, amounting to £3,000 to £4,000; it had suffered greatly through the effects of last year's coal and railway strikes. The report and accounts as given in our last issue were adopted, the election of Mr. Fred S. Sells to the Board was confirmed, Mr. L. G. Byng, who retired from the Board by rotation, was re-elected a director, and a vote of thanks to the Chairman and directors concluded the proceedings.

**Edmundsons' Electricity Corporation.**—A progressive improvement was reported by the Chairman at the annual meeting last week. The net result of the past year's trading was a balance of £18,899, compared with £16,114 in the previous year. The connections during the year have increased by the equivalent of 161,782 35-watt lamps, compared with 126,522 in the previous year.

**R. Waygood and Co.**—An issue of 15,000 each of preference and ordinary shares is to be made.

**Newcastle-on-Tyne Electric Supply Co.**—An interim dividend at the rate of 5 per cent. per annum is recommended on the ordinary shares for the half year.

## NEW COMPANIES

**ELECTRICAL ENGINEERING & MOTOR CO. (Carlisle).** Capital, £3,000. Suppliers of electricity, &c.

**WIRELESS ELECTRIC LIGHT CO.,** 6 Broad Street Place, E.C. Capital, £75,000. Electric lighting and general engineers and contractors.

**EASTERN SPAIN DEVELOPMENT SYNDICATE,** 101 Leadenhall Street, E.C. Capital £16,000. To acquire and work concessions for railway electricity supply, &c. First directors Sir Murland Evans, Baron von Horst, E. Parey, A. Ross, and J. Chapman. Private company.

**WIRELESS TELEPHONES, LTD.,** 62 London Wall, E.C. Capital £500. To acquire inventions relating to transmission of signals, &c.

**GALASHIELS & DISTRICT ELECTRIC SUPPLY CO.,** 23 Rutland Street, Edinburgh. Capital, £30,000.

Telephone No.: 5509 Holborn.

Cheques to be made payable to THE KILOWATT PUBLISHING CO., LTD., and to be crossed LONDON COUNTY AND WESTMINSTER BANK (Temple Bar Branch).

## SUMMARY

NOTES on the arrangements for the next session at some of the Universities and Technical Colleges are given on page 430.

A DEMONSTRATION of two "truckers," and an explanation of the scheme proposed by the New Transport Co. for an electrically operated Goods Clearing House for London was given last week. (Page 431.)

AMONG interesting exhibits at the Olympia Commercial Vehicle Exhibition are the 40 h.p. Tilling Stevens omnibuses, &c., and the Delahaye military travelling workshop. (Page 431.)

THE opposition by Mr. W. P. Durnall to the grant of a patent to the Oerlikon Co. for multiphase current drive in self-contained vehicles has been successful. A report of the hearing before the Comptroller is given. (Page 432.)

A LETTER from Mr. Hope Jones points out that the new scheme of international wireless time signals is not yet completely in force. (Page 432.)

SOME electrical novelties are described on page 432.

THE routine testing of storage batteries is treated in our questions and answers columns. (Page 433.)

A REPORT of a Paper on automatic signalling is contained in our Electric Traction Notes, where reference is also made to the deficit on the West Ham Tramways, and the decision to use petrol electric trams at Oxford. (Page 434.)

A SHORT description is given under "Telephony and Telegraphy," of the Lorimer automatic telephone exchange which has been installed at Hereford.—It has been decided that the deferred shareholders of the National Telephone Co. are entitled to the whole of the surplus assets, but this decision may be appealed against. There has been considerable correspondence regarding the suitability of the Poulsen system of wireless telegraphy for long distance work. (Page 435.)

A SPECIFICATION for a new design of heat lagged horizontal cylindrical oven by Haydn T. Harrison, was published by the Patent Office last week. Among the other specifications were two dealing with the mounting of metal filaments by the Julius Pintsch A.-G. and the Austrian Westinghouse Co. respectively, while a system of combined steam flow and electrical meters for use in a generating station to see that each boiler contributes its share of the load is protected by the B. T.-H. Co. A patent covering diatriene insulated paper cables, by H. Edmunds, of W. T. Glover & Co., expires this week after a full life. (Page 436.)

THE Post Office tube railway has passed through the Committee stage of the House of Commons. A limitation has been placed upon the use of current for lighting post offices, and a modified electrolysis clause has also been inserted. (Page 434.)

AT a Board of Trade inquiry last week relating to the proposed transfer of the Cromer electricity undertaking to Edmundsons' Electricity Corporation, the inspector intimated that certain of the conditions proposed could not be included in the agreement.—The Diesel engine scheme at Bedford is not to be proceeded with at the present time, but experiments with oil-burners under the existing steam boilers are to be tried.—A Board of Trade inquiry has been held at Swanage, when objections to the proposed Diesel engine generating station were heard.—A proposal by the Cardiff Corporation to the effect that a balance of £5,962 standing to the credit of the Electricity Committee should be used for the erection of workmen's dwellings, was negatived.—A new switchboard has been constructed by the staff of the Taunton Electricity Works. (Page 437.)

A 3,000 kw. turbo-alternator, rotary converters, and E.H.T. switchgear are required at Norwich.—An E.H.T. feeder panel is required at Warrington, and switchboards at Middleton.—Mains extensions are

projected at Hastings, St. Anne's-on-Sea, Wolverhampton, and Southend.—Plant extensions and electric lighting schemes are being investigated at Bristol, Dungarvan, Hereford, Hamilton, and Southend. (Page 437.)

THE net profit for the half-year of the Yorkshire Electric Power Co. is £7,616. A six per cent. dividend on the cumulative preference shares is recommended, and the waste heat power station at Barrugh will soon be completed. An issue of  $4\frac{1}{2}$  per cent. mortgage debentures is being made by the Bristol Tramways and Carriage Co. (Page 438.)

**Electricity Supply in London.**—The Special Committee which was appointed by the L.C.C. some time ago to investigate the steps to be taken to co-ordinate the sources of electric supply in London, in view of the Council's ultimate acquisition of the electric companies' undertakings, has now reported its intention to make arrangements at an early date for obtaining reports which, *inter alia*, will (1) deal with the existing means for the supply of electricity in Greater London; (2) give an outline of a complete ultimate scheme for Greater London, and indicate what modifications would be required in any such scheme if it were limited to the County of London; (3) include a definite recommendation as to the initial steps to be taken in the direction of a complete scheme, bearing in mind the existing conditions and the general financial position. In this connection a recommendation is made to the Council to authorise an expenditure of £2,500 in obtaining expert assistance.

**The Ontario Hydro-electric Scheme.**—We learn from the *Electrical World* (New York) that several serious breakdowns have occurred recently on the Ontario Hydro-electric Commission's system. On June 16th the service on the Commission's Toronto system was interrupted for over seven hours, during which time the whole of the load was taken by the Toronto Electric Co., which provided an emergency supply within an hour. On July 2nd there was again a failure of the transmission line to Toronto, which necessitated the power being cut off again for seven hours. We also learn that from June 1st to 26th there were 13 interruptions, totalling 28 hours. Mr. H. H. Couzens, late chief electrical engineer, Hampstead, who has just taken charge of the Ontario Hydro-electric scheme, apparently has a busy time before him to devise arrangements for preserving continuity of supply, both internally and by arrangement with competing schemes.

## UNIVERSITY AND TECHNICAL COLLEGE ANNOUNCEMENTS

The 1913-14 session of the University of Liverpool, Faculty of Engineering, commences on October 7th, when very complete courses in engineering will start. The subjects embraced include electrical engineering, under the direction of Professor E. W. Marchant, civil and mechanical engineering, naval architecture, design and drawing, chemistry, &c. The Special Matriculation examination or the Entrance examination must be passed to secure admission to the courses of instruction. Full particulars may be obtained by application to the Registrar, Mr. P. Hebblethwaite.

The syllabus of the University of Birmingham, with details of University regulations, lecture and laboratory courses, fees, scholarships, &c., may be obtained on application to the Secretary. It may be noted that the full courses in one or other branch of engineering extend over four years, and students who enter after Matriculation and pass successfully the examinations at the end of each year will be entitled to the B.Sc. degree in the branch of engineering to which they have devoted themselves. Professor Gisbert Kapp is the head of the electrical engineering department, and Sir Oliver Lodge is the Principal of the University.

The next session at the University College, Nottingham, begins on September 29th, when courses preparing for the B.Sc. (Engineering) degree of the London University, and the B.Sc. (Mining) degrees, as well as for the College diplomas, may be taken. The usual courses extend over three years. For particulars and prospectus application should be made to the Registrar, Mr. T. P. Black.

In October a systematic course of instruction in electrical measurement and practical electricity will be commenced in the electrical department of the University College of North Wales (Bangor). The laboratory is well equipped with machinery and apparatus. The Secretary and Registrar, Mr. J. E. Lloyd, will be pleased to supply further information as to the course, which extends over two sessions.

Full particulars of the many courses embracing engineering, naval architecture, mining, metallurgy, agriculture, pure science and commerce, to be obtained at the Armstrong College (University of Durham), which is situated at Newcastle-upon-Tyne, may be obtained on application to the Secretary, Mr. F. H. Pruett. The next session commences on September 29th.

## THE COMING HALF-WATT LAMP.

(See article in last week's ELECTRICAL ENGINEERING, page 416.)

What will not happen next autumn at any rate.

What should happen next autumn.

## THE PROPOSED NEW ELECTRICALLY-OPERATED GOODS CLEARING HOUSE

ON Wednesday last week the New Transport Co., Ltd., entertained a number of people at a demonstration in their Battersea works of machinery and models relating to the goods clearing house (ELECTRICAL ENGINEERING, Vol. VI., p. 445; July 7th, 1910), which it is proposed should be established in Clerkenwell.

It was pointed out that there are in London eleven railway companies, owning seventy-four goods stations and receiving about 320 goods trains per twenty-four hours. These 320 trains require over 700 daily inter-goods-station trains merely to "sort" the various railway wagons into other London stations or shunting yards. At each of these stations each bale of goods in a railway wagon is then sorted into the various delivery vans by porters with hand-trucks. By substituting one central goods clearing house, as designed by the New Transport Co., for the seventy-four goods stations, the 700 daily inter-goods-station trains could be saved, London railway tracks could be relieved of these, and most of the land now occupied by the seventy-four goods stations could be redeemed. The sale of this land alone would, it was said, be sufficient to pay for several goods clearing houses. The area covered by the proposed clearing house is 30 acres. The main reasons which render this concentration possible and economical are:—(1) The clearing house has eight floors; (2) The unloading and re-loading of wagons is performed rapidly by cranes lifting whole wagonloads at one hoist, obviating the shunting of wagons in sidings; (3) The sorting of bales, &c., is performed by automatic machinery instead of by porters wheeling hand-trucks; (4) The street collection and delivery service is one organisation, and is frequent and regular.

Below street-level run twenty-four railway berths, parallel to each other, from end to end of the clearing house, each long enough to accommodate a seventy-wagon goods train, and connected with the railways serving London. Over these, on the street-level, twelve road bridges cross at intervals from side to side of the clearing house. A road vehicle can thus be brought over any desired rail vehicle, and a load can be transferred from the one to the other by an electric overhead crane. Below the rail level is a crypt, in which whole wagonloads are sorted, and, if necessary, temporarily stored until a train is ready to receive them. Above the road-bridge level are four sorting floors, and above these an eighth floor with offices and repair shops. Of the sorting floors, two are for bales up to 10 or 12 cwt., and two are for parcels up to about 15 lb. In order to save time in loading and unloading, a whole wagonload is dealt with at one lift by a crane, by using a "container." Each sorting floor is divided into compartments called "bays," at each of which goods for a particular town, &c., are delivered by the sorting machinery, consisting of endless trains of machines called "truckers"; these move continuously at three miles per hour, and trays bearing goods are automatically slid without concussion on to them at despatching stations, and off them at receiving stations. Transfers are also made to truckers running on an adjacent line of rails at six miles per hour to connect with the various systems of slow-speed truckers. An arrangement of hoists also connects the floors and automatically takes the goods. The "marching orders" are given to each trucker by dispatchers, of whom there may be any number working independently in different places. Each operation is controlled by circuits through push-buttons on the dispatchers' tables, which operate a contact ratchet wheel on the truckers. This wheel closes a control circuit in one position only, and is provided with one tooth for every station, and if in a case there were thirty stations, and it was wanted to stop at, say, the eleventh station from the dispatching station, the ratchet would be moved on nineteen teeth by closing the control circuit for that station through the push-button. Every time the trucker passed a station the controller would be moved on another tooth, until at the eleventh it would close the control circuit and stop itself. Similar arrangements apply as to the transfer of goods from one trucker to another while one is overtaking the other, and as it is provided for the control circuit of the first to be completed through the second, then, if the second one is already loaded, the circuit on this is not continuous, so that the circuit controlling the electro-magnetic rollers, which transmit the platform containing the goods from one trucker to the other, cannot be completed, and no transfer takes place. The rollers are set at an angle to the front of the truckers, so that at the standard

speed of progression there is no relative motion of the goods in the direction of travel of the truckers during the transfer. The rollers are kept out of contact with the goods container or platform, except when the circuit is complete for a transfer to take place, when they become energised and grip the tray by magnetic attraction. They rotate with uniform acceleration and retardation every time two truckers pass. This is done mechanically by means of cams and followers on the truckers themselves, which come into engagement.

Although the system is always talked of in relation to a goods clearing house for London, yet it is applicable to the handling of goods and parcels of all kinds, such as are dealt with by the Post Offices, large stores, &c., as well as smaller railway undertakings.

## THE COMMERCIAL VEHICLE EXHIBITION

IN view of the renewed interest in the electrically-propelled vehicle which has followed the introduction into this country on a commercial scale of the long-promised Edison battery, and the fact that it is the propulsion of a certain class of commercial vehicle that opens up one of the most promising fields for its use, it is regrettable that it has not been found possible to include a single battery-driven vehicle in the Exhibition of Commercial Motor Vehicles now being held by the Society of Motor Manufacturers and Traders at Olympia.

Electrical engineers will find the most interesting stand to be that of W. A. Stevens, Ltd. (26 Victoria Street, Westminster), which is devoted to examples of the latest patterns of the now well-known Tilling-Stevens petrol-electric omnibuses and other vehicles. The display includes, a 40-h.p. chassis, a complete double-decked bus, a char-a-banc and lorry with the same equipment. The 40-h.p. equipment is on the same lines as that of the 30-h.p. omnibuses running in London, except that the generator and electric motor are not in line (see ELECTRICAL ENGINEERING, Vol. VII., p. 41, Nov. 23rd, 1911), but the motor is placed lower down, and, owing to the greater length of chassis, further from the motor. This is done mainly to keep the platform level as low as possible. Each machine, as before, is provided with its own fan. The chassis shown is arranged so that the motor can be driven by a few Edison cells, and the action of the switch-gear demonstrated. The only differences in the control from former models are the situation of the reversing and field controllers on the front of the dash inside the bonnet worked by levers conveniently mounted on the steering column, and the provision of a motor field as well as a dynamo field resistance. These two resistances are worked by the same controller and give rather greater range than before. Some interesting records taken by a Wimpey Accelerometer show the great superiority of the electrical transmission system over the ordinary gear and clutch from the point of view of stresses to which the vehicle is subjected. Under identical conditions the peaks in the curve are much higher with the mechanical gear. The curves show that the intermittent accelerations on the gear-driven vehicle exceed 8 ft. per sec. per sec., resulting in a strain on the road wheels exceeding 560 lb. per ton in the gear-driven bus, while in the Tilling-Stevens omnibus in no place does the line show an acceleration of 3½ ft. per sec. per sec.; therefore the transmission strains on this vehicle are certainly less than 245 lb. per ton on the road wheels, although in the test on which the records were taken the Tilling-Stevens vehicle was driven considerably faster than the gear-driven omnibus. The braking strains are about the same on each vehicle. In the Tilling-Stevens vehicle it is impossible for the driver to accelerate beyond a certain limit, although, as the acceleration is continuous, the vehicle can attain a given speed more rapidly than any other omnibus of the same rating. It is, however, impossible to limit the shocks to which an ordinary gear-driven vehicle can be subjected by the operation of the clutch and gears. In addition to the saving in upkeep of chassis and body in the Tilling-Stevens petrol-electric omnibus, a great saving is made in tyre renewals. In the London service an average distance of 20,148 miles per tyre has been obtained.

Another exhibit to which attention may be drawn is the Delahaye military travelling workshop, shown by H. M. Hobson, Ltd. One of these has already been ordered for the Royal Flying Corps. The engine which drives the car is employed for driving a dynamo when the vehicle is stationary. The dynamo in its turn drives separate electric motors on each machine, such as lathe, drilling machine, grinder, shaping machine, bent and circular saws for woodwork. Besides this, the inside of the car is very completely fitted with fitter's and carpenter's bench and full complement of

tools for all work in connection with the repair and maintenance of military aeroplanes in service.

In the accessories section in the gallery several firms show car-lighting dynamo equipments, but no striking novelty in this direction makes its appearance.

### THE "PARAGON" TRANSMISSION SYSTEM PATENTS

AN interesting opposition case by Mr. W. P. Durnall against the grant of a Patent to the Maschinenfabrik Oerlikon was argued before the Comptroller-General of Patents on Friday last.

Mr. Durnall, it may be remembered, claims to hold the master-patents for the system of driving and control by polyphase current adjustable pressure and frequency in self-contained vehicles. This system has been given the name of the "Paragon" system. The claims in two of Mr. Durnall's specifications (Nos. 17,248 of 1905 and 23,396 of 1908) which he cited in the present case are given here, as well as the claim in the Oerlikon Co.'s specification No. 19,890 of 1912, which is the one opposed.

The claims in Patent No. 17,248 of 1905, granted to E. W. Hart and W. P. Durnall, read as follows:—"(1) In a method of propelling a vehicle or boat comprising the combination of a prime mover, an electric generator, a motor in electrical connection therewith, and appropriate transmission gear, the use of an electric generator having a revolving magnet or magnets and a stationary armature, the windings being arranged for polyphase alternating currents. (2) In a method of propelling a vehicle or boat, as claimed in Claim 1, adapting the exciter so that the excitation of the electric generator field-magnet or magnets may be varied, substantially as and for the purpose described."

In Patent No. 23,396 of 1908, granted to W. P. Durnall, there are 12 claims. The first claims "A plant for the generation of polyphase electric currents of varying periodicity by means of a prime mover or movers, which may run at a constant speed, said plant comprising a polyphase transformer-generator, which has its rotor coupled mechanically to a prime mover, and a polyphase alternator which serves to excite the primary of said transformer-generator, and is coupled to the same or to another prime-mover than that to which the said rotor is coupled, substantially as described." The remaining claims deal with constructional details. Corresponding to this specification is the German specification numbered 230,406 of 1911.

The claim in the Oerlikon Co.'s specification, No. 19,890, of 1912, which was only recently published (ELECTRICAL ENGINEERING, Feb. 6th, p. 80, and April 3rd, p. 192), is for "An electric locomotive, motor-boat, and the like in which the driving shaft motors are fed by a generator moving with the locomotive, or the like, coupled with a driving engine such as a steam turbine, Diesel engine, or the like, characterised by the fact that the generator supplies motors, having short-circuited armatures, with multiphase current, and the velocity of the motors is governed by regulating the velocity of the driving engine within its economical limits, while for starting, stopping, and reversing, the motors are governed by known controlling devices in their circuits."

Mr. Durnall claimed that Patent No. 17,248 of 1905 is a master-patent, but Mr. Bosshardt, jun., on behalf of the Oerlikon Co., maintained that this could not be, as the claims began by the words "In a method . . ." The Comptroller pointed out that the claims might have been made clearer, and that they would always be open to the objection that only the use of particular machines was implied. He thought, however, that, though the broad reading of the claims of specification No. 17,248 of 1905 might be old, yet even on the narrow reading the Oerlikon Co. were practically claiming what was claimed there over again with a slight modification. A direct reference to No. 17,248 of 1905, but not to No. 23,396 of 1908 would be necessary in specification No. 19,890 of 1912, and he would have to consider whether if, after that were done, there was sufficient invention left to justify the grant of a patent. He would notify his decision on this point later.

**Large Research Laboratory.**—An Electrical Research Laboratory and Bureau is to be established in connection with the Massachusetts Institute of Technology. Its official title will be "Division of Electrical Engineering Research," and taking into account the library an endowment of over 200,000 dollars (£42,000) is assured. The investigations will be carried out by trained experts, and will be of a practical character, and embrace illumination, telephony and telegraphy, and traction. The greatest distance a passenger can be economically carried on a tramcar for a given fare, is to be considered, as well as the handling of freight on railroads, and like questions.

### CORRESPONDENCE

#### INTERNATIONAL TIME SIGNALS.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—Users of the "Hörphone" and others among your readers who have wireless installations have been puzzled by the time signals transmitted from Paris and Norddeich since July 1st. They are not in conformity either with the new or the old scheme, but appear to be a combination of both.

I therefore wrote to le Commandant Ferrié, of the Eiffel Tower Station, for an authoritative statement on the subject. He has kindly complied, and I have pleasure in communicating a translation of part of a letter just received from him:—

"I have the honour to inform you that the new International Signals established by la Conference de l'Heure in October last, and which were to have been employed commencing from the 1st July, could not be inaugurated at the date fixed, for the following reason: The German technical services have announced that certain material difficulties would prevent the time Station of Norddeich from being ready before the month of October at the earliest. As the Station of Norddeich now sends the time at midnight, and as according to the new conventions the Eiffel Tower ought also to send the time at midnight, there would result a jamming of the two emissions. So we have had to delay putting into operation the decisions of the Conference. Nevertheless, we send the new automatic time signals at 10 a.m., according to the new Conventions, in order to give practice to people who take the time. We continue, however, to send the time as formerly at 10.45 a.m., and 11.45 p.m. with the old signals. We were ready to operate on the 1st July, as is shown by the fact that we commenced the new morning signals on that date, but it is by courtesy that we have delayed putting into practice the whole of the new International arrangements."

It appears to be no one's duty to inform wireless telegraphists in this country as to international services of this kind, and we should therefore be grateful to Commandant Ferrié for this prompt but unofficial communication.

Yours faithfully,

F. HOPE-JONES.

32 and 34 Clerkenwell Road, E.C.

### ELECTRICAL NOVELTIES

WE are now able to illustrate the pocket lamp in the shape of a pistol being put on the market by the General Electric Co., Ltd. (67 Queen Victoria Street, E.C.). The "pistol" is very compact, and has no sharp edges to tear the pocket. The two-cell battery is contained in the stock, and the switch is worked by the trigger. Various new

OSRAM PISTOL.

designs in pocket lamps, torches and lanterns have also been recently introduced by the Company. Osram drawn-wire battery lamps are used in every case, and thus, even the smallest size lamp gives the maximum efficiency.

Another novelty consists of a small turbine, coupled direct to a magneto-generator giving 8–10 volts (about 12 watts). It can be coupled to a main water tap, and will be found suitable for lighting lamps, working small models, &c.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,348.

A double pole circuit-breaker is required for a 500 ampere, continuous-current, 100-volt supply circuit. The double-pole switches are to be operated by means of a solenoid (mounted vertically) through a toggle mechanism. The switches are to be jammed against the contacts in the "On" position. Give a suitable design for the toggle mechanism and switch contacts, &c., showing how the "holding on pressure," and the "initial pull" to operate the solenoid can be ascertained. No automatic safety devices are required in the circuit breaker.—"B. C."

(Replies must be received not later than first post, July 31st.)

### ANSWERS TO No. 1,346.

Describe a regular course of routine inspection and testing for a central station battery of about 250 cells of say 1,000 ampere hours' capacity at the five hour rate; (a) with end regulating cells, and (b) without end regulating cells.—"NASCENT HYDROGEN."

The first award (10s.) is given to "M.M." for the following reply:—

The method of procedure is practically the same in either case, allowance being made when taking the voltage of each individual cell; cells that are cut out of circuit are not subject to the C.R. drop. Regulating cells are often neglected in ordinary tests, and sometimes suffer through over-charging. It may happen that the end cells are rarely in use, and if not cut out early in the charge they run the risk, particularly with pasted plates, of being injured. Over-charging is by no means an unmixed blessing for pasted plates; with a heavy current flowing through charged cells, the paste tends to become loosened, and thus trouble is started. Each cell of a battery should be numbered, and notes taken, and a record kept of its condition and performance. The following points should receive careful attention:—

**Specific Gravity of Electrolyte.**—The usual density is 1.170 when the cell is empty and 1.200 when the cell is fully charged. All the cells of a battery should show a similar figure; where one or two differ from the rest it is certain that something is wrong. A cell that does not pick up by the next examination should be cut out of discharge and joined up again for the charge; this often puts things right. There should be sufficient electrolyte in the cell to reach about half an inch above the top of the plates. For filling up cells, or, as it is called, "topping," distilled water should be used.

**Electromotive Force.**—Each cell should never fall below 1.8, and when being charged should not reach a higher voltage than 2.65. There is sometimes a tendency for attendants to take the voltage of the battery as a whole, and from this calculate the volts per cell, but such a method should not be tolerated; each cell must be separately tested, as if there is one, or are even two, bad ones, they may easily be missed.

**General Conditions.**—When going round the battery, connections should be examined for evidence of corrosion, insulators examined, any tendency to buckling of the plates noted, and

careful watch kept for "sulphating." Where connections are corroded they should be repaired, and any doubtful contacts cleaned and overhauled. When plates show buckling they may often be straightened by means of a strip of hard wood pushed down between the plates; the plates are easily bent, and with the aid of a few wood packing pieces it will be found possible to work wonders. One of the surest indications of the condition of a cell is the colour of the plates. Good cells have the negatives lead colour, with positives a distinct chocolate; if the positives are losing their colour this points to incipient sulphating. To get rid of this white deposit is always a troublesome process, therefore it should be treated in its early stages; the only sure preventative is to charge fully and regularly. Any nostrums for the purpose are best left alone—simply employ volts.

Generally, it is most important to keep a record of the weekly test in order to satisfactorily diagnose the condition of a faulty cell; its previous history should be known before deciding on any definite treatment. Too much stress cannot be laid on the importance of thorough tests and examination; in many cases testing is little more than perfunctory.

The second award (5s.) is made to "SPARKO," who writes as follows:—

The regular course of inspection and testing for a central-station battery should be the same whether end regulating cells are used or not. But when end cells are used, they are specially liable to become unevenly discharged, and therefore require more attention than the remainder of the cells. They are successively cut into service on the discharge; hence, on the charge, they should be successively cut out in the reverse order, otherwise the ones that were last cut in will be overcharged. Special care should be taken in regard to this, as it is easy to forget that a number of the cells were not cut out into circuit until probably near the end of the discharge, and then require but a small proportion of the amount of charge required for the main battery. In order to secure satisfactory operation of a battery, each of the cells should be inspected at regular intervals. The voltage of individual cells may become low, the electrolyte may not be of the proper specific gravity, or foreign substances may become lodged between the plates, or in the bottom of the cells; and regular inspection is necessary to locate any such defects that may develop. Such readings as are taken from the cells should be recorded in such a way that consecutive readings may be easily compared; if a cell is acting irregularly, the fact will then be at once apparent. Each cell should be thoroughly inspected at least once a month. When examining a cell, great care should be taken to look between all the plates, and any accumulation of material should be removed at once, possibly by pushing same to the bottom of the containing vessel, by means of a stick of wood. A metal rod should never be used in a storage cell, as it would cause short circuits and do damage. In addition to the above examination of the cells, an inspection should be made near the end of each charge to see if all the cells are gassing freely, and readings of voltage and specific gravity of the electrolyte should be taken at the end of each prolonged charge, while the current is still flowing. If any of the cells show readings lower than the normal and do not gas freely at the end of the charge, they should be examined at once to determine the cause of the falling off. Very likely it is due to short circuiting between the plates, caused by a lodgment of material in the intervening space, or else by an accumulation of mud in the bottom of the cell. A cell that has become low will usually require more than the usual amount of charging to get it into condition again after the cause of the trouble has been removed. A simple method of doing this is to cut the low cells out of circuit over one or two discharges, and then cut them in on the charges. Before putting the defective cell into service again, care should be taken to see that all signs of a full charge are present. Care should also be taken with regard to the specific gravity of the electrolyte, which is indicated by the hydrometer. When the cells are fully charged, the specific gravity of the electrolyte should be from 1.2 to 1.24 at 60° F. The final density on discharge should not fall below 1.15, and from 1.185 to 1.195 is the usual practice.

**Restaurant Lighting.**—We have received from the British Thomson-Houston Co., Ltd. (Mazda House, 77 Upper Thames Street, E.C.) a photograph of the Eustace Miles Restaurant, where the lighting is scientifically carried out by means of Mazda drawn wire lamps, equipped with moulded prismatic glass diffusing reflectors, which almost completely hood the lamps. The units are suspended about nine feet from the floor, so that they are out of the direct field of vision, and give an efficient even distribution of the light, so that the effect is very pleasing.

## CATALOGUES, PAMPHLETS, &c., RECEIVED

**SILVERTOWN MANUFACTURES.**—An interesting illustrated pamphlet from the India-rubber, Gutta-percha & Telegraph Works Co., Ltd. (Silvertown, E.), gives some historical notes on the development of the works and its manufactures, and illustrates both the machinery employed and the articles turned out in the various departments. Thus in the rubber department the washing-machines, mixing-mills, &c., are described, and mention is made of the various waterproof articles, hose, belting, floor covering, &c., made, and a description is given of the manufacture of Palmer cord tyres; similarly ebonite articles, including fountain-pens, and gutta-percha articles, including golf-balls, are dealt with. Several pages are devoted to the submarine cable department, and examples of the dynamos, motors, electric vehicles, cables, instruments, batteries, searchlights, &c., made in the electrical department, are illustrated, and a good idea is given both of the extent and up-to-dateness of the company's operations.

**MOTOR CONVERTERS.**—The instructive pamphlet dealing with the well-known Peebles Motor Converter has just been revised and brought entirely up-to-date by Bruce Peebles & Co., Ltd. (Edinburgh), who are the manufacturers of these machines. Among the several fine illustrations is one showing the interior of one of the sub-stations of the Calcutta Electric Supply Corporation, where are seen six of the nineteen 475 kw. three bearing sets supplied. As well as illustrations showing individual machines, there are diagrams of connections, which enable one to appreciate the simplicity of the motor-converter, which may be used direct on high pressures, and characteristic curves proving the high efficiency over a wide range of load. The principle of the motor-converter is fully treated, and it is shown that these machines are equally suitable for traction, lighting, or combined loads, as well as for three-wire balancing. We are informed that during the past eighteen months orders have been received for over 60 sets, in sizes ranging from 1,500 kw. down to 100 kw.

*Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."*

**SWITCHGEAR, &c.**—New lists have been issued by A. Reyrolle & Co., Ltd., Hebburn-on-Tyne, dealing with potential transformers in iron cases for oil filling, and with watertight plugs and sockets for mines, shipyards, &c., providing for a separate earth conductor in the flexible cable, as called for by the Home Office Regulations.

**MOTORS AND DYNAMOS.**—A well-arranged list is to hand from Wright & Wood, Ltd. (Century Works, Halifax), dealing with continuous-current motors and dynamos, two- and three-phase induction motors, starting gear for continuous- and alternating-current motors, motor-generators, rotary converters, &c., and portable polishers and saw benches.

**SILICA LAMPS.**—A revised sheet from the Westinghouse Cooper-Hewitt Co., Ltd., shows that a 2,500 c.p. unit for 110 volts has been added to the already comprehensive range of these lamps. The full range is now from 800 m.h. c.p. to 3,000 m.h. c.p. The burners have an average life of about 4,000 hours, and are renewable at a small cost.

**WEATHERPROOF LANTERNS.**—A sheet from Krupka & Jacoby, Ltd. (26 to 36 Chapter Street, Westminster, S.W.), brings to notice neat designs of single light weatherproof lanterns for round metal filament lamps of 100-1,000 c.p.

**The Post Office Tube Railway.**—The House of Commons Committee last week passed the preamble of the Bill which authorises the Postmaster-General to construct a tube railway, for the purposes of the mail service, from the East to West London. There was considerable discussion on clauses, and among the opponents were the electric lighting companies of London, as mentioned in our last issue. With regard to the objection taken to the Postmaster-General lighting post offices anywhere in London, a clause was inserted at the instance of the Post Office limiting the supply of electricity to the railway and to post offices on the line of route or within 50 yards of it. Another question discussed on clauses was in relation to electrolysis. Owing to the strong objection felt to placing one Government department under the control of another, it was not proposed to insert the model clauses dealing with electrolysis, under which the Board of Trade Regulations have to be complied with. Instead, a clause was proposed under which the Postmaster-General would be liable to pay compensation for any damage done if he had not taken reasonable precautions to obviate damage, there being, of course, an appeal to arbitration to settle the amount of any damage so alleged. The Committee decided that under the circumstances this clause should be inserted in the Bill.

## ELECTRIC TRACTION NOTES

Some interesting notes on the A.C. method of automatic track-circuit signalling for railways were contained in a recent Paper read before the Students' Section of the I.E.E. by Mr. T. J. Hornblower (Mackenzie Holland and Westinghouse Power Signalling Co., Ltd.). It will be remembered that this is the system installed on the East London Railway and now being installed on the Central London Railway. It is also extensively used in America and on some Continental lines, as the possibility of interference by stray currents is reduced to a minimum. The track is divided into insulated sections connected by impedance bonds as shown in Fig. 1 at  $S_1, S_2$ , so that the power current can pass while the signalling current cannot. The track pressure is usually between  $1\frac{1}{2}$  and 3 volts at 25 cycles if the traction current is direct, or 60 cycles if it is alternating. A relay controlling the signals is connected across the rails at the beginning of the section, and so long as the track is unoccupied the relay circuit is held open; but when shunted by a train being in the section, the relay circuit is closed. Some of the difficulties met with in practice are that the ballast resistance (insulation between the rails) may vary between 1 ohm and 10 ohms per

FIG. 1.

FIG. 2.

1,000 ft. The track is fed through a special transformer so as to obtain approximately constant current irrespective of the ballast resistance. A transformer with rapidly falling characteristic, or a transformer with an inductance, or thermal regulator in series may be used. The latter consists of iron wires in bulbs of hydrogen, which, as is well known, have a peculiar temperature-resistance characteristic which make them eminently suitable for this work. Three types of relay are in use: (1) the "vane" type, in which a pivoted aluminium vane moves between the poles of a shaded magnet; (2) the "galvanometer" type, which works on the same principle as the Siemens dynamometer and is useful for long block sections, and (3) the "centrifugal" type, which consists of a Pickering governor worked by a little squirrel-cage motor. Semaphores are usually worked by a small A.C. motor to the "clear" position and held there, with the motor current cut off, by an electromagnet until the control current is cut off, when the arm returns to "danger" by gravity. A diagram of the ingenious red and green lamp signal circuits used on the East London Railway (ELECTRICAL ENGINEERING, April 11th, 1912, p. 194, and March 20th, 1913, p. 165) is given in Fig. 2. It is usual for the supply-current for the green lamp to be taken off from a 100-volt tapping on the transformer, the red lamp being supplied at only 16 volts so as to eliminate all possibility of a short between the red and green leads causing the green lamp to light up. The green lamp is placed in series with one winding of a small transformer. The other winding is connected across the leads for the red lamp in series with an adjustable resistance  $R$ . The red lamp is put as a shunt across the coil as shown. The red circuit is left on continuously, and when the green circuit is open the impedance of  $S_1$  is so high that the red lamp lights up. When the relay closes the green circuit the magnetising force of  $S_2$  opposes that of  $S_1$ , so that there is no flux produced in the core. The impedance of  $S_1$  is then only very small, and the red lamp is extinguished. An adjustable resistance  $R$  allows the ampere-turns in  $S_1$  and  $S_2$  to be made equal.

*Elektrische Kraftbetriebe und Bahnen* for April 14th contains a long article by Herr G. Brecht, one of the chief engineers of the Prussian State Railway Department, on the traffic capacity of terminal stations. He concludes that the adoption of electric traction on city or suburban lines increases the capacity of terminal stations by at least 50 per cent. as compared with steam traction.

There was a deficit of £3,388 on the West Ham Corporation Tramways for the year ending March 31st. In the previous year there was a surplus of £4,082. In his evidence a short time ago, before the House of Commons Committee which is considering the question of motor traffic in London, Mr.

# ADAMS IGRANIC

MOTOR CONTROL GEAR FOR STEEL MILLS.

ADAMS  
MFG CO LTD  
BEDFORD  
AND  
LONDON

H. E. Blain, late General Manager of the West Ham Corporation Tramways, foreshadowed that there would be a considerable loss this year in consequence of motor-bus competition.

The Oxford Corporation has accepted the scheme proposed by the National Electric Construction Co. for the use of petrol-electric tramcars in the centre of the city, with overhead wires in the outskirts.

At the last meeting of the London County Council, attention was called to the fact that last year Parliamentary expenses amounting to £32,000 were involved in securing powers to construct 31½ miles of tramways, or roughly £1,000 per mile.

## TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

The July issue of the *Post Office Electrical Engineers' Journal* contains a detailed description of the automatic exchange equipment on the Lorimer system, manufactured by the Canadian Machine Telephone Co. of Toronto, which has been installed by the British Post Office at Hereford. The equipment is for 500 lines, and is arranged in five switching units. Provision is made for seven simultaneous outgoing and seven simultaneous incoming calls per 100 subscribers.

The Lorimer system has considerable differences from the Strowger system, which is used at the other automatic exchanges in this country, and unlike the latter involves continually rotating shafts. To make a call, the subscriber adjusts four levers to the correct figures, turns a handle, and lifts his receiver. The number thus set can be, so to speak, stored up if all the switches are engaged, and connected up automatically in proper sequence. The caller always has before him the number he has set his apparatus to, so that a mistake can be detected. Other special features are that the line of the calling subscriber is searched for and found by the wipers of the "A" or line-finding switch; the calling line does not directly find a disengaged switching apparatus, but a disengaged switching apparatus is brought into action to find the calling line; there is no up and down movement of the switches as a separate wiper is provided for each level of contacts. Also a time-limiting device is provided, which can be adjusted to limit conversations to a definite length of time, and to prevent one subscriber holding up another by failing to restore his receiver. In the earlier Lorimer equipments, a continuously running "decimal indicator" was used as well as the other moving switches described below, but in the Hereford equipment this has been replaced by line and cut-off relays. When a call is received, the action of the line relays and the "division starter," and "decimal controller," is to find the calling line and connect it to a pilot switch. This then brings the signal controller switch into action to ascertain the numbers set up at the calling telephone, and to adjust the ringing and inter-connector registers. During the passage of the wiper over the first part of the signal controller cylinder, impulses are sent over line 2 of the calling subscriber's circuit, and these operate his mechanism. While the impulses are passing, a feed relay tests the second wire connected to the subscriber's moving brush, and the ringing register records the number of impulses sent out before the position of the thousands lever is found by the brush. The ringing register thus joins up the particular ringing commutator for ringing up the called subscriber. The inter-connector register is next brought into circuit, and on the operation being repeated records the number of impulses sent out before the position of the hundreds is found. The inter-connector switch then finds a junction line to the required hundreds group. The pilot switch is then signalled, and moves on, causing the signal controller and test relay to repeat their operation to ascertain the tens and units, and the wipers of the B switch come to rest on the required contacts. The signal controller pauses while the pilot makes the busy test, and when signalled by the busy test relay, the signal controller signals to the pilot to move after a brief pause to the ringing position. Finally the pilot switch moves to the talk position, and on

the subscriber hanging up it passes to the release position, and the various switches are brought to normal.

In reply to further questions in the House of Commons last week, the Postmaster-General explained how, when the Advisory Committee on the Marconi contract had investigated the various systems, difficulty was at first experienced by the Universal Radio Syndicate (Ltd.) in obtaining the use of the Eiffel Tower, which they had hoped to do. On application by the British Government, the French Government had eventually allowed the use of the Eiffel Tower, but difficulty was experienced in accommodating the apparatus, so that the tests were never carried out. The Postmaster-General also stated that he had received a telegram from the British Consul-General at San Francisco, informing him that the Company were not yet able to conduct any daylight service at all to Honolulu. The cost of the twelve masts for each of the proposed Marconi wireless stations would be about £33,000, but he did not know the cost of masts for the Goldschmidt system. A letter in *The Times* of July 19th, by Mr. A. S. Baxendale, managing director of the Universal Radio Syndicate, points out, among other things, that a regular daylight service is being conducted from San Francisco to Honolulu, but the non-completion of the Honolulu end has so far prevented a similar service being given in the opposite direction. The Postmaster-General has replied at length, and disclaims all responsibility for the Poulsen Syndicate not being able to secure the opportunities for demonstration which they desired. He had, he says, now received a copy of Dr. Austin's report, but it was not such as to cause him to reject the advice given by Lord Parker's Committee. Sir Joseph Larmor, in a letter, remarks that it seems unreasonable to assign some of the stations in the wireless chain to one company and the remainder to another, and he asks how is it to be decided whether a station is using a patent belonging to a special system, and therefore liable to pay royalty? He also advocates that the Advisory Committee be made permanent like the Advisory Committee for Aeronautics.

Mr. Justice Sargent decided last week that the deferred stockholders in the National Telephone Co. are entitled to the whole of the Company's surplus assets, which amount to about £200,000. This decision was given on an originating summons taken out by the liquidator in the voluntary winding-up of the Company, to determine what construction was to be placed on old and new articles and resolutions passed on the creation of the various classes of the Company's stock. Mr. Justice Sargent held that the first, second and third preference shareholders were only entitled to the return of paid-up capital, and the preferred stockholders were not entitled to any interest. Mr. George Franklin, the liquidator, has since pointed out that pending the result of a possible appeal against Mr. Justice Sargent's decision, he has been authorised to make early distribution to the deferred stockholders of a further payment of 4s. 4d. in the £. This will account for approximately £820,000 of the remaining assets, amounting to some £1,131,250.

An improved wireless installation is being installed at Port of Spain, Trinidad, the old plant having been found insufficient to deal with growing requirements. The new plant consists of a 5-kw. Marconi apparatus, and is designed for a working range of about 400 miles by day and 1,000 miles by night.

The Administration of Montenegro has closed the telegraph office at St. Jean-de-Medova.—On the 17th inst the Sebastopol-Varna cable failed, cutting communication between Russia and Bulgaria, and was restored on the 18th inst.—The Roumanian Administration notifies the control of offices at Turtucaia and Silistria by them, and the renaming of the stations as Turtucaja and Silistria. They further say that the prohibition of code and cypher only applies to private telegrams, and not to those between Legations.—On the 22nd inst, communication was down with Capelongo, Cassinga, Gambos, Cahama, Humbe, Cuamato, Ancongo, Damequero, Donguena, Cafu, Evale, Quiteve, and Mulondoin Angola.

# "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

## Specifications Published July 17th, 1913

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in *italics> indicate communicators of inventions from abroad.*

15,065/12. **Ovens.** HAYDN T. HARRISON. A horizontal cylindrical vessel is surrounded by another, and the space between the two is heat lagged. The sides and top of the inner vessel merge gradually so as to present no surface which abruptly deflects ascending currents of heated air. The shelves, framework, and heating elements are removable *en bloc*, and they may be turned so as to alter the relative position of the elements in the oven. An opening is made in the top of the oven, and provided with a cover, so that cooking utensils may be heated if desired. Seven figures.

15,404/12. **Storage Batteries.** E. SOKAL. An improved construction for storage batteries where the electrolyte circulates under pressure is described. Hollow and partly hollow electrodes are so arranged that the length of the edge which is to be secured against leakage is materially decreased. A single pump without reservoirs is all that is required to keep up the circulation. The electrodes are arranged concentrically so that the inner and outer surfaces may be used.

15,485/12. **Incandescent Lamp Filament Supports.** JULIUS PINTSCH. At the ends of the spider arms transverse cross-pieces are provided so that the filaments may be loosely held in place without fastening. Ten figures.

17,247/12. **Floor Lamps.** G. MAURICE and L. G. BYNG. (G. E. Co.) The lamps are arranged entirely within an opaque reflector, which conceals them, and throws the light upward. Flower or plant holders are arranged sloping outwardly round the reflector. Three figures.

18,747/12. **Vibrating Rectifier.** B. T.-H. Co. (G. E. Co., U.S.A.). The armature is provided with a damper consisting of a spring which prevents its being operated by current from the battery (being charged through the rectifier), and a second spring to bring the armature to rest near one of the poles of the A.C. magnet. One figure.

21,725/12. **Telephone Holder.** G. J. STERN. A two-armed pivotted lever of such design as to actuate the hook switch of the set by a slight movement which also brings the receiver into the exact position for hearing, is provided. The lever is made in two parts, and is attached to the pillar of the set by a clip bracket. Four figures.

22,262/12. **Boiler Output Indicators.** B. T.-H. Co. (G. E. Co., U.S.A.). Where there are a number of boilers feeding into a common header which is supplying steam to a number of generating sets, a steam flow meter shows the output of each boiler, and a second meter shows the total output of the generators, while others situated near each boiler indicate the share of the total load each boiler should carry. To this end an ammeter is connected to one of the busbars. This ammeter is shunted by another through an adjustable resistance, and is the master ammeter in series with other auxiliary ammeters adjacent to the respective steam flow meters. One figure.

26,288/12. **Incandescent Lamp Filament Supports.** WESTINGHOUSE METALLFADEN GLÜHLAMPENFABRIK. Some of the resilient arms which radiate from the central stem are longer and stronger than the remainder, or else a disc, ring, star, or similar contrivance may be fixed on the stem near the radiating arms. This is made of greater diameter than the arms. By either of these methods the danger of breakage of the spider during its introduction into the bulb is reduced. Two figures.

2,136/13. **Control of Motors Driving Screw Propellers.** SIEMENS-SCHUCKERT. Shunt or compound motors are used, and the armatures are switched direct into circuit. The series winding may be fed direct or through a transformer. In the former case a self-induction is used in series with the armature. The shunt winding is always energised.

4,197/13. **Buzzers or Hooters.** E. A. GRAHAM. To obtain a distinctive sound of a sharp or snappy character from a vibrating diaphragm, impacts are transmitted from an electromagnetically operated striker to it indirectly through a hammer lever by a spring, which tends to separate the striker from the lever, and the lever from the companion anvil on the diaphragm. Thus, by the mutual reaction, very abrupt movements are obtained. Two figures.

## Petition for Extension of Term of Patent

24,048/99. **Telautographs.** F. RITCHIE. Mr. Justice Warrington has fixed October 27th as the earliest day on which the petition by the National Telewriter Co., Ltd., shall be in the paper for hearing.

## Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

**Dynamos, Motors, and Transformers:** E. C. Co. and PENSABENE [Dynamos and motors] 7,651/12; CLAUDIUS ASH, SONS, & Co., JONES and LEE [Transformers] 2,697/13; SIEMENS BROS. (*Siemens & Halske*) [Arrangement of current transformers for high pressures] 8,027/13.

**Electrometallurgy and Electrochemistry:** THE GOLDSCHMIDT A.G. [Alumino-thermic rail bonding] 218/13.

**Heating and Cooking:** MARKS (*Landers, Frary and Clark*) [Toasters] 15,961/12.

**Incandescent Lamps:** JULIUS PINTSCH [Filament supports] 15,486/12; TRUSS, 23,453/12; PAKENHAM, 24,361/12.

**Instruments and Meters:** NORTH [Instrument testing] 16,730/12; BECKMANN [Polyphase movement indicator] 130/13.

**Switchgear, Fuses and Fittings:** B. I. Co. and ALLWOOD [Junction boxes] 15,706/12; MCPHERSON [Thermal switches] 20,464/12; LONGFORD and CLARK [Terminals] 20,775/12; SIEMENS BROS. and LE CORNEY [Submersible watertight insulating plugs] 28,646/12; GILL [Automatic control of artificial illumination] 29,928/12.

**Telephony and Telegraphy:** CLAUSEN [Telephony] 15,057/12; AITKEN [Telephone exchanges] 15,292/12; BLACKWELL and ANDEREGG [Reducing telephonic disturbances] 2,508/13; SIEMENS BROS. and PETTITHORY [Electro-magnetic telephone service meter] 2,752/13; GRISSINGER [Telephone repeater systems] 2,930/13; KESSELS [Keyboard telegraph transmitter] 3,582/13.

**Traction:** KREBS [Lighting vehicles] 16,024/12.

**Miscellaneous:** HAILWOOD [Miners' safety lamps] 3,903/12; ARON and WIENER [Clock winding] 9,154/12; HADDON (*Stewart & Clark Mfg. Co.*) [Speedometers] 23,597/12; MASCHINENBAU-ANSTALT HUMBOLDT [Electro-magnetic separators] 24,643/12; BARLOW [Locking gates of electrically-controlled lifts, &c.] 25,258/12; ENGLE [Primary batteries] 3,861/13.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Dynamos and Motors:** SIEMENS-SCHUCKERT., 14,390/13; OERLIKON Co. [Apparatus for winding] 14,633/13.

**Telephony and Telegraphy:** SIEMENS & HALSKE [Selectors for automatic or semi-automatic telephony] 13,748/13; SIGNAL GEN. [Submarine electric leakage telegraphy] 13,919/13.

**Miscellaneous:** HARLÉ ET CIE [Submarine mines] 13,807/13.

The following Amended Specification may now be obtained.

2,325/12. **Automatic Railways.** J. J. DESCHAMPS.

## Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:—

15,418 of July 27th, 1899. **Paper Insulated Cables.** H. EDMUNDS (Glover & Co.). The object of the invention is to lessen the weight of paper-insulated cables, and to do away with the necessity for the lead sheath. To this end the paper is saturated with a mixture of resinous matter and oxidised oils of a sealing and waterproof character, e.g., the material known as a "diatrine." Alternating with this paper is paper treated with an oily matter or a lubricant. The whole is taped or braided, and again treated with "diatrine" or its equivalent.

The following are the more important Patents that have become void through non-payment of renewal fees.

**Dynamos and Motors:** J. E. NOEGGERATH [Construction of homopolar machines] 6,752/05; [Current collecting and lubrication of homopolar machines] 7,045/08; E. S. G. REES [Frame construction for high-speed three-bearing machines] 7,725/06.

**Ignition:** D. E. BROWN and C. A. VANDERVELL [Rotary contact breaker] 20,897/08.

**Incandescent Lamps:** G. T. HOLLOWAY and H. W. LAKE [Tungsten and alloys] 6,045/00; A. G. BLOXAM (*J. Lux, Vienna*) [Sintered tungsten filaments] 7,803/06; A.E.G. [Squirted colloidal tungsten filaments] 7,407/07.

**Instruments:** S. EVERSHED [Cell-testing voltmeter] 7,955/02.

**Storage Batteries:** T. A. EDISON [Manufacture of negative electrodes for alkaline cells] 1,926/06; [Nickel hydroxide electrodes for alkaline cells] 1,927/06.

**Telephony and Telegraphy:** I. KITSEE [Submarine and long-distance telegraphy, using a special relay and sounder] 7,586/04.

**Miscellaneous:** G. E. GAFFE [Rotary mercury interrupter] 19,477/07; A. SCHIESS [Automatic fire extingisher] 7,384/08.

## LOCAL NOTES

**Bedford: Diesel Engine Inquiry.**—Judging from a report of the Electricity Committee submitted to the last meeting of the Corporation, the Diesel engine scheme is not now to be proceeded with, at any rate for the present, and the Engineer has received permission to experiment with oil burners for the boilers with a view to increasing the emergency output. Alderman Kilpin, Chairman of the Electricity Committee, pointed out that, even if the loan were granted, the Diesel engine could not be obtained in time for the coming winter, and the course above suggested had been hit upon to carry the undertaking over the winter.

**Gardiff: Electricity Profits.**—An extraordinary proposal was made at the last meeting of the Corporation by one of the Councillors to the effect that the balance of £5,962 standing to the credit of the Electricity Committee should be used for the erection of workmen's dwellings. We are pleased that the Committee's recommendation that the sum should be retained and carried forward as a working balance was agreed to.

**Cromer: Proposed Transfer of Electricity Undertaking.**—The Hon. T. H. Pelham held an inquiry last week at Cromer on behalf of the Board of Trade with regard to the proposed transfer of the electricity undertaking to Edmundsons' Electricity Corporation. At present the Company runs the works under an agreement with the Corporation, which is for a term of twenty-five years, under which the Company meets the repayment and interest on a loan of £25,000, and undertakes to keep the plant and machinery in a good state of repair. Under the proposed transfer now, the Company will purchase the undertaking on a cash basis, paying off the balance of the loan for which the Council is responsible. The inspector intimated that any conditions as to street lighting, as was suggested, could not be included in an agreement for the transfer of the undertaking. Evidence was given by a number of Councillors and others against the proposed transfer, but it came out that the real opposition was not so much to the transfer as to the obtaining of a sum of money apart from the amount to be paid to the Council in return for the release from the existing agreement. The inspector, however, pointed out that this was a policy which was not allowed by the Board of Trade.

**London: Poplar: Electrolytic Disinfectant.**—Since the electrolytic disinfectant plant was installed by the Council in connection with the electricity works about seven years ago, nearly a quarter of a million gallons have been manufactured, at a cost for electricity and materials of about £480. Last year the output was 54,388 gallons, and the average cost was slightly less than ½d. per gallon.

**St. Pancras: Electricity Accounts.**—The net profit on the last year's working of the electrical undertaking was £10,686, which is a decrease of £1,752 from the previous year, and £2,518 less than 1910-11. To this profit the balance of £6,307 from last year is added, bringing the balance to the credit of net revenue account to £16,992.

**Mansfield: Electricity Profits.**—A sum of £600 is to be taken from the profits of the electricity undertaking last year for the relief of rates.

**Norwich: Electricity Accounts.**—A satisfactory year's working of the electricity undertaking was reported at the last meeting of the Corporation, there being a net profit of £6,353 for the year to March 31st. The average price obtained was 1.78d. per unit, which is just half the figure of ten years ago.

**Nuneaton: New Plant.**—A new 700-kw. B.T.-H. turbo-generator was started up last week.

**South Shields: Electricity Accounts.**—The net result on the past year's working was a surplus of £3,163, compared with £2,195 in the previous year.

**Swanage: Electricity Works.**—A Board of Trade inquiry has been held in regard to objections raised to the proposed site of a generating station by the Swanage Electricity Supply Co. Mr. A. P. Trotter, Electrical Adviser to the Board of Trade, acted as inspector, and Dr. J. A. Purves, Consulting Engineer to the Company, explained that Diesel engines would be installer, and that there was no possibility of annoyance to anyone from vibration. Mr. Sydney Morse, who appeared on behalf of the Company, said he would give an undertaking to use every effort to make the station so perfect that there could not be any complaint whatever from any of the residents.

**Taunton: New Switchboard.**—In presenting the electricity accounts at the last meeting of the Corporation, the Chairman of the Electricity Committee drew special attention to the fact that a new switchboard had been constructed completely by the staff at the works. It was in all respects similar to one which he had seen at Kingston-on-Thames, for which the contract price was £2,000.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

## Generating Stations, Sub-Stations, Mains, &amp;c.

**Aberdare.**—An inquiry has been held concerning a loan of £2,453 for extensions at the power station.

**Bristol.**—A Local Government Board inquiry has been held concerning a loan of £25,000 for the electricity undertaking. Of this, £18,000 are required for mains; £2,500 for sub-stations, and £4,500 for house services. There was some opposition by the Ratepayers' Association, but the inspector, towards the end of the inquiry, said that most undertakings had gone through hard times in recent years, and Bristol was no exception. The best thing to do was to reduce capital charges by increasing the output, or by using the profits so as to avoid further borrowings.

**Dungarvan.**—An electric lighting scheme, at an estimated cost of £2,600, is under consideration.

**Hamilton.**—Extensions at the electricity works at an estimated cost of £2,190 have been approved by the Council.

**Hastings.**—Mains extensions are to be carried out at an estimated cost of £120.

**Hereford.**—The Rural District Council has consented to the Corporation supplying electricity in the district of Holmer.

**London: Bermondsey.**—The Finance Committee of the L.C.C. recommend sanction to a loan of £8,682 for electrical extensions.

**Middleton.**—Lighting switchboard and renewal of traction switchboard. Borough Electrical Engineer. July 28th.

**Norwich.**—One 3,000-kw. turbo-alternator, condensing plant, rotary-converter, and E.H.T. switchgear. (See an advertisement on another page.)

**St. Anne's-on-Sea.**—A loan of £3,000 for mains and services has been inquired into. There was no opposition.

**Southend.**—Mains extensions are to be carried out at an estimated cost of £176. A loan of £365 is to be applied for to purchase an additional economiser for use in connection with the two Niclausse boilers which it is proposed to instal at the power station.

**Warrington.**—E.H.T. feeder panel. August 6th. Borough Electrical Engineer.

**Wolverhampton.**—Mains extensions at an estimated cost of £254 are to be carried out.

## Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

**Aberdeen.**—Baths scheme to cost £25,000.

**Barnes.**—New covered swimming bath.

**Cardiff.**—New technical institute, Cathays Park. Architects, I. Jones and P. Thomas, 18 St. Mary's Street.

**Cheltenham.**—New municipal offices.

**Dundalk.**—Rebuilding of Great Northern Railway Co.'s carriage shops.

**Eastbourne.**—New cinematograph theatre.

**Glasgow.**—Shops and business premises in High Street area. Town Clerk.

**Heckmondwike.**—Electric wiring of new slaughter-house. July 28th. Architect, H. Stead.

**Hull.**—Wiring and fitting of school for fishermen. City Architect.

**Pontefract.**—Block of shops and arcade. Architects, Garside & Pennington.—New cinematograph theatre. Architect, W. J. Tennant.

**Sheffield.**—New Infants' Department at Morley Street school. Secretary, Education Department.

**Weybridge.**—New fire station.

## TENDERS RECEIVED AND ACCEPTED

Messrs. Johnson & Phillips have secured the following orders for their standard type oil-cooled transformers during the last few weeks:—Two 625-k.v.a. 6,600-volt for Dundee Corporation; one 500-k.v.a. 6,600 volt for Oldham Corporation; two 150-k.v.a. 6,000-volt for Wigan Corporation; three 100-k.v.a. 2,000-volt for H.M. Admiralty; fifty-one 50-k.v.a. and three 300-k.v.a. 13,200-volt for Canada; four 400-k.v.a. 10,000-volt for Japan; two 350-k.v.a. 6,000-volt for Brazil. They have also secured upwards of 5,000-k.v.a. in transformers for English machinery makers in connection with converting plants, &c.

## APPOINTMENTS AND PERSONAL NOTES

Mr. E. P. Grove, Chief Engineer of the Central London Railway until its absorption into the London Underground Combine, was presented on Tuesday last with a cup by some eighty friends, most of whom had assembled at the Trocadero to give him a farewell prior to his departure to Australia. Mr. Grove is going out as the Australian representative of Mr. C. H. Merz, Consulting Engineer to the Victorian Government for the Melbourne electrifications, and in that capacity will superintend the electrification of the Melbourne suburban system. Mr. H. N. May will accompany him to deal particularly with rolling stock. The gathering on Tuesday was presided over by Dr. H. F. Parshall, Consulting Engineer to the London Underground Combine. Mr. A. L. C. Fell, Mr. Frank Baily, Mr. C. P. Sparks, and Mr. D. Hay were among those present.

A number of friends having expressed a wish to celebrate Mr. Wyld's appointment as Chief Electrical Engineer to the Borough of Hampstead, and to welcome both Mr. and Mrs. Wyld to London, a dinner will be held on Friday, October 3rd, at Oddenino's Imperial Restaurant, Regent Street, W. As the dinner is to welcome both Mr. and Mrs. Wyld, single tickets will be issued for gentlemen only, and double tickets for lady and gentleman. Early applications for tickets should be made to Mr. C. Newton Russell, 29 Southwood Avenue, Highgate, Chairman of Committee, or to the Hon. Secretary and Treasurer, Mr. E. P. Barfield, "Porlock," Athenaeum Road, Whetstone, N.

The salary of Mr. A. W. Blake, Electrical Engineer to the Willesden Urban District Council, has been increased from £300 to £350 per annum, with a further increase of £50 on April 1st, 1914.

The salary of Mr. J. A. Robertson, Burgh Electrical Engineer at Greenock, has been increased from £500 to £550 per annum, with an additional increase of £50 when Port Glasgow is linked up with the Corporation's supply.

Mr. R. H. Schofield, who has been with Messrs. Ferranti, Ltd., for nearly eighteen years, has been appointed Sales Manager. His headquarters are Central House, Kingsway, London, W.C.

An electrical engineer is required by the Waterford Council for the preparation of an electric lighting scheme. (See advertisement on another page.)

An assistant lecturer is required in the Electrotechnics Department of the Borough Polytechnic, London. (See advertisement on another page.)

A demonstrator in Electrical Engineering is wanted at the City and Guilds (Engineering) College. (See an advertisement.)

## John E. Raworth,

Queen Anne's Chambers, Chartered Patent Agent.  
30, Broadway, Westminster, London, S.W.

## MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. G. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of copper, c.i.f. port of arrival, quoted on Tuesday night, was £66 5s. to £66 15s. (last week the same).

**New Showrooms.**—Customers and friends of Ferranti, Ltd., are invited to visit the firm's new showroom at Central House, Kingsway, London, W.C., which contains a representative display of meters, detail switchgear, oil switches and electrical heating and cooking apparatus, including the new domestic oven.

**Switching Competition.**—A. P. Lundberg & Sons (477-487 Liverpool Road, Islington) write us that their switching competition, to which we referred on page 404 of ELECTRICAL ENGINEERING of July 10th, is not only limited to wiremen and students, but is open to all, including users of electric light.

**A Prize Van.**—The General Electric Co. has sent us an illustration of one of their motor vans with decorations, including a tableau of "Aladdin and the wonderful Osram Lamp," which won a prize at a recent carnival at Ilford.

Following on its success last week at the Ilford Hospital carnival, the decorated Osram van secured the first prize for decorated vehicles at Willesden on Thursday at the annual carnival in aid of the local hospitals.

**Works Holidays.**—The works of T. W. Broadbent, Ltd. (Victoria Electrical Works, Huddersfield), will be closed from Friday night next till Tuesday morning. No goods can be despatched between these dates.

The works of the London Electric Firm will be closed from Saturday, Aug. 2nd, till Monday, Aug. 11th. A small staff, however, will deal with urgent business.

The Trafford Park Works of the British Westinghouse Electric & Manufacturing Co., Manchester, will be closed from Friday evening next to Tuesday morning, August 5th. No goods can be despatched between these dates, but a small staff will attend to matters of extreme urgency.

The works of Cryselco, Ltd. (Bedford) will be closed from Saturday, August 2nd, until Monday, August 11th.

**Canadian Agency.**—A Midlands company manufacturing electrical appliances wishes to arrange for a Canadian agency. Further particulars, 73 Basinghall Street, E.C.

**Bankruptcies.**—A receiving order has been entered against F. Johnson, Electrical Engineer, 60 Eltisley Avenue, Newnham, Cambridge.

## COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

**Yorkshire Electric Power Co.**—The net profit for the June half year, including £644 brought forward, was £7,616. The half year's dividend on the 6 per cent. cumulative preference shares is recommended, carrying forward £4,308. The waste heat power station at Barrugh will shortly be at work, and will when completed add a further 5,000 kilowatts to the company's generating station.

**Electric Construction Co.**—At the annual meeting last week the chairman of the company spoke in very optimistic terms as to the future of the electrical industry in general, and to the Electric Construction Co. in particular.

**Bristol Tramways & Carriage Co.**—An issue of £250,000 4½ per cent. mortgage debenture stock at 92½ is being made.

## NEW COMPANIES

**ELECTRICAL APPARATUS CO., (1913),** Vauxhall Works, South Lambeth Road, S.W. Capital, £90,000. To take over the existing business of the Electric Apparatus Co., Ltd.

**JACKSON ELECTRIC STOVE CO.,** 38 Blandford Street, Baker Street, W. Capital, £10,000.

**MACINTOSH CABLE CO.**—Registered by Jordan & Son, 116 Chancery Lane, W.C. Capital £25,000.

## SUMMARY

REPORTS have been issued by Committees of the Illuminating Engineering Society on the lighting of schools and libraries. (Page 440.)

NOTES on the arrangements for the next session, &c., at some of the Universities and Technical Colleges are given on page 440.

THE programme of the meetings of the International Electrotechnical Commission to be held in Berlin at the beginning of September, has been issued. The special committees on nomenclature, rating, and prime movers will submit their recommendations to the working session of the whole commission, whose resolutions will afterwards be ratified at a plenary meeting. (Page 440.)

MUCH useful and interesting information is contained in an article on the experience in connection with a comparatively new single-phase railway in Norway. What practically amounted to systematic experimental research as to the methods of preventing or neutralising

the disturbance to telephones was carried out on the line itself, with successful results. The article also relates how certain vibration troubles on the conductors, due to the low frequency ( $16\frac{2}{3}$  cycles per sec.), were overcome. (Page 441.)

A NEW pattern of oil-immersed, drum-type, star delta starter, which is fitted with no voltage and overload releases, and a handle arranged so that it cannot be held on when the releases act, nor be left in the star position, is described and illustrated. (Page 442.)

FULL particulars are given of the construction of a form of wet air filter for use with turbo-generators. The air is thoroughly washed by a fine spray, but an elaborate system of baffle plates removes all suspended water. (Page 442.)

VERY considerable extensions to the electricity works are proposed at Bradford by the City Electrical Engineer, Mr. T. Roles. They have been approved and adopted by the City Council. The immediate installation of a 3,000-kw. turbo-alternator and the abolition of the obsolete steam sets will be carried out. Additional rotary converters and a large storage battery are included in the programme, while in a few years larger turbo-alternators will be installed. By this means there is sufficient space for extensions in the Valley Road works to avoid building a new generating station for some ten years. (Page 443.)

AN outline of the successful visit of the I.E.E. Students' Section to the Newcastle district a short time ago is given. (Page 443.)

A SOMEWHAT novel lighting installation exemplifying a combination of several systems of illumination is referred to on page 444.

A NEW spacing saddle for supporting conduit tube clear of the wall has been introduced. (Page 444.)

A PUBLICATION relating to wireless telegraphy is reviewed. (Page 444.)

THE procedure to be adopted in a central station case of a feeder fault in particular circumstances is discussed in our Questions and Answers columns. (Page 445.)

A PATENT by A. Swan relating to the manufacture of incandescent lamps expires this week after a full life.—A. M. Taylor is seeking leave to amend his specification relating to frequency changing by static transformers.—J. Stone & Co. also desire to make considerable amendments to a specification by H. D. Earl, in which an automatic regulator for variable speed dynamos is described.—The grant of two patents to J. B. Le Maitre for cinematograph targets, which was opposed, has been allowed, subject to the specifications

being amended.—Several specifications relating to incandescent lamps and one to rotary converters having more than one armature winding were published by the Patent Office on Thursday last. (Page 446.)

An important decision has been made by the House of Lords regarding the rating of tramway undertakings, which are held not to be entitled to be rated as railways, even when authorised under the Light Railways Act. This is referred to under Electric Traction Notes, where particulars are given of a 2,400 volt continuous-current railway in America, and the proposed conversion of the Brussels suburban railways to high-voltage continuous-current traction. (Page 447.)

MR. W. DUDELL is to be retained permanently by the Government in an advisory capacity regarding wireless telegraphy. Some modifications have been made in the scheme of royalties in connection with the Marconi contract.—Other matters referred to under Telephony and Telegraphy are the new selective or heterodyne receiver developed by Prof. Fessenden, a new French system of wireless telegraphy by waves of very great length, and some successful results in long-distance wireless telephony. (Page 447.)

ADDITIONAL protective gear is to be installed in the L.C.C. Greenwich power station, in view of the recent breakdowns.—The results of the financial working of the past year of several electricity undertakings are now available. Profits have been made at West Ham, Burslem, Hanley, and Stoke, but the accounts of Kingston-on-Thames and Longton show losses.—The surplus at Edinburgh is to be devoted to reduction of capital account and not to relief of rates. (Page 449.)

A TURBO-ALTERNATOR is required at Bury. Extensions are projected at Long Eaton and Doncaster, and the Local Government Board has now sanctioned the loan for the new power station at Bolton. Tenders are invited at Dublin for pumps, pipe-work, &c. (Page 449.)

FIVE per cent. dividends have been declared by the County of London and Charing Cross Supply Co.'s., and a four per cent. dividend by the Metropolitan Electric Supply Co.—The Brush Electrical Engineering Co. has made a considerable loss on the year's working. (Page 450.)

### LIGHTING OF SCHOOLS AND LIBRARIES

THE Joint Committees appointed in 1911 by the Illuminating Engineering Society to investigate both daylight and artificial lighting of schools and libraries have just issued preliminary reports dealing with artificial lighting. The Committee dealing with school lighting heard evidence on the systems of direct, indirect, and semi-indirect lighting and suggests that the following standards of illumination should be provisionally adopted irrespective of the method of lighting:—(a) for ordinary clerical work (reading and writing, &c.), the minimum illumination measured at any desk where the light is required, should not fall below 2 foot-candles; (b) for special work (art classes, drawing offices, workshops, and stitching with dark materials, &c.), a minimum of 4 foot-candles is desirable; (c) for assembly rooms, &c., and for general illumination a minimum of 1 foot-candle measured on a horizontal plane 3 ft. 3 in. from the ground. The question of the permissible diversity factor remains to be considered. For small class-rooms where no student is more than 20 ft. from the blackboard, and if white chalk is mainly used, an illumination of 2 foot-candles may be sufficient, but the Committee recommend that, in general, an illumination on the blackboard 60 per cent. in excess of that prevailing in the rest of the room is desirable. Attention is also drawn to the advisability of the avoidance of glare and of inconvenient shadows.

The Committee dealing with the lighting of libraries finds that table, desk, or newspaper stand lighting should in no case be less than 2 foot-candles where ordinary type on white paper is being read. Where small type or where the reflecting power of the paper is low a tentative value of 5 foot-candles is suggested. For bookcase and shelf lighting a

minimum vertical illumination of  $\frac{1}{2}$  foot-candle is advocated. This value is also suggested as adequate for the general illumination—read on a horizontal plane 3 ft. 3 in. above the floor. No definite system of lighting is advocated, but screening of bright light sources is recommended, as well as the avoidance of reflection from the surface of paper or tables, and the avoidance of shadows. It is proposed to supplement these reports by a series of more detailed recommendations, and also by some suggestions as regards daylight illumination.

### UNIVERSITY AND TECHNICAL COLLEGE ANNOUNCEMENTS

THE programme of the City and Guilds Technical College, Finsbury, shows that the next session will commence on October 7th, and that the entrance examination will be held on September 16th. The subjects of this examination are English and mathematics, and there are several scholarships and free studentships awarded on the result. The Principal of the College and Professor of the Electrical Department is Dr. S. P. Thompson, while Dr. E. G. Coker is Professor of Civil and Mechanical Engineering, and Dr. Raphael Meldola is Professor of Applied Chemistry. All the departments have recently been considerably enlarged, and facilities for numerous experiments and original researches are afforded, while for students desiring to carry out special investigations a third or fourth year's course in electrical or mechanical engineering was recently started. Certificates are awarded to students who have satisfactorily worked in either department for the minimum period of two years, while the award of a diploma or higher certificate to students who have attended courses for three years are under consideration. All communications on the subject of the educational work of the College, and the admission of students, should be addressed to the Principal, City and Guilds Technical College, Finsbury, Leonard Street, London, E.C.

The International Correspondence Schools have opened an exhibit of their new series of technical pocket-books at their headquarters, International Buildings, Kingsway, W.C. These handy little works of reference, published at 5s. each, may be obtained for a limited period by those interested in technical or business matters at 1s. 6d. each, at the exhibition only.

The hundred and twenty-second award of certificates to students of the Crystal Palace School of Practical Engineering will be made in the school to-day at noon by Mr. W. B. Bryan (Chief Engineer to the Metropolitan Water Board).

We understand that the Royal Commissioners for the Exhibition of 1857 have awarded an Industrial Bursary to Mr. J. Y. Rudd, who has just completed a course of study in the Engineering Department of the University of Bristol. A similar Bursary, awarded to Mr. S. L. Hall in 1912, has been renewed for a further year, and the Bursary awarded to Mr. A. J. S. Pippard in 1911 has been continued for a further period of two months.

### INTERNATIONAL ELECTROTECHNICAL COMMISSION

THE preliminary programme of the meeting which is to be held in Berlin from September 1st to September 6th, under the presidency of Dr. Budde, has been issued. The Special Committees on Nomenclature, Symbols of Electrical Machinery, and Prime Movers, which have been working continuously since the Turin meeting of 1911, are to hold meetings prior to those of the full Commission. In order to have an opportunity of discussing the latest modifications to their reports, suggested by the National Committees, these meetings will be held on Monday, September 1st, and the following day. The results of these meetings will be embodied in reports which will be considered at the working sessions of the whole Commission on the Wednesday and Thursday. The formal opening and presidential address will take place on Wednesday, September 3rd, and a distinguished German official will present the address and welcome to the foreign delegates. A banquet is to be given by the German Committee in the evening. The plenary meeting will be held on Friday, September 5th, when the various resolutions drawn up by the working sessions of the whole Commission will be submitted for ratification. In the afternoon a meeting of the Council will be held, and it is probable that the presidency of the Commission, which would have been conferred on M. Mascart if he had lived, will be offered to an eminent French electrical engineer. An all-day excursion is to be arranged for the Saturday.

## OPERATING EXPERIENCES AND TELEPHONE TROUBLES ON THE RJUKAN SINGLE-PHASE RAILWAY

THE Rjukan railway was constructed in 1907 by the Norwegian Nitrate Company to connect their large factories at Rjukan with the shipping station of Notodden. It is a full-gauge, single-track goods line, 28½ miles long, divided into two sections by a lake, over which the trains are carried by a steam ferry service.

On the longer section from Notodden to Tinoset there is a length of 2½ miles with a gradient of 2·7 per cent., and there are numerous sharp curves. A comparatively light rail of 50·5 lb. per yard was adopted, the maximum axle load being limited to 11 tons. At present the traffic consists of only three to five trains per day in each direction. The maximum train weight is about 260 tons, and the maximum speed only 20 miles per hour.

Electric working was commenced in January, 1910, after two years of steam operation, the reasons for electrification being the extremely low cost of electric power, the heavy gradients and the possibility of reducing the train staff. The line was equipped by the A.E.G., of Berlin, on the single-phase system at 10,000 volts, 16½ cycles, with similar equipment to that supplied for the London Brighton & South Coast Suburban electrification, and the operating experiences have therefore a particular interest for British engineers.

The Nitrate Company's power stations generate at three-phase, 10,000 volts, 50 cycles, and two substations were therefore put down for the railway supply at Notodden and Rjukan respectively. The former contains three and the latter two 350-kw. motor-generator sets, the single-phase machines generating direct at the trolley pressure of 10,000 volts. The overall efficiency of these sets at full load and 0·85 power factor is 0·83, including losses in the transformers on the three-phase side, but the average overall efficiency of these substations would not be more than 50 per cent. As it is calculated that the power supplied to the substations costs only 0·13d. per unit, this low efficiency is not so serious as it looks at first sight.

The overhead equipment is carried out with a single catenary and single insulation, and there are no positive or negative feeders except the connections between the substations and the trolley wire and rails respectively. The trolley wire has a section of 0·1 sq. in. The cost of this equipment, covering steel masts, brackets, catenary, trolley wire, and span wire construction at the stations, is said to have been only £400 per mile of line (copper at £65 per ton).

The present rolling stock consists of five locomotives, three of 500 h.p., each with four 125-h.p. motors, and two of 250 h.p. with two motors. One transformer is provided for each pair of motors. The latter are of the Winter-Eichberg type, operated at 220 volts, and have a power-factor of 0·8 when running at full load and 15 miles per hour. They are arranged two on each bogie, and are geared to the driving axles with a ratio of one to 4·22. A more detailed and well-illustrated description of the equipment is given by Dr. Marguerre in *Elektrische Kraftbetriebe u. Bahnen* of December 4th, 1912.

No working costs have as yet been made public, but some interesting operating experiences have been published. On opening the line in January, 1910, considerable trouble was experienced through telephone and telegraph disturbances, in spite of the fact that these had been foreseen and various special precautions taken. The effects produced and the methods adopted for overcoming them are described at length in the *Elektrotechnische Zeitschrift* of November 21st, 1912. As a rule there is only one train running on one section of the line and the current in the trolley wire is about 40 amperes. On the heavy gradient it is about 60 amperes, while at starting it may be 70 or 80 amperes. The calculated pressure drop with 60 amperes over a distance of 15½ miles is 580 volts, consisting of 380 volts in the trolley wire and 200 volts in the heavily bonded rails. It was realised that this would result in a considerable earth current, and as a precaution all the single telegraph or telephone lines in the neighbourhood of the railway were provided with a metal return. In spite of this, however, the 16-cycle current caused numerous call-bells within a wide zone to ring continuously. Trouble was also experienced from electromagnetic and electrostatic induction, and it was found necessary to alter slightly the run of some sixty miles of telephone and telegraph circuits so as to make them parallel to the trolley wire; to ensure that all were transposed at frequent intervals; and to insert cross-connected inductive resistances earthed at their mid-points (four or five in every mile of line) to lead the unbalanced induced currents to earth. To avoid any trouble from higher harmonics in the single-phase pressure and current waves, it was specified that the amplitude of any harmonic in the pressure wave of the single-phase generators should not exceed 4 per cent.

of the fundamental, and the locomotive motors were constructed with "skewed" slots. In spite of this, however, there was a steady noise to be heard in the telephones when no locomotive was working, and this increased to a serious extent when a train was started or was running. As the tone remained the same always it was clear that neither the motor slots nor commutation were responsible for this noise, and later, with the aid of an oscillograph, it was traced to the generator slots. It was found that these were responsible, on inductive load, for a harmonic with an amplitude 17 per cent. of the fundamental, which affected the telephone lines both by electromagnetic and electrostatic induction. It was not possible to alter the pole shoes of the generator to eliminate this, but the trouble has been practically overcome by the use of cross-connected inductances of lower resistance and larger inductance than is usual, and by the partial absorption of the harmonic in a resonance circuit, formed by connecting across the terminals of the single-phase generator a combined capacity and inductance, thus short-circuiting the machine for the high slot frequency of about 560 cycles. This latter device has been so successful that now only the starting of the locomotives is heard on the telephones, and that not to any serious degree.

Besides these difficulties with telephone lines, a great deal of trouble was experienced with the rolling stock after a few months of working, chiefly from mechanical causes. The motor pinions and gear wheels were found to be of too soft a material, and this, coupled with the pulsating torque resulting from the low electrical frequency, caused them to wear down very rapidly. This wear was accelerated by the breaking of the welded gear cases and oiling devices, due to the severe vibration. The vibration was also the cause of numerous electrical troubles. The transformer coils rubbed against each other until the insulation was chafed through, and this necessitated the reconstruction of all the transformers so as to ensure rigidity. Again, the breakages of the pipes conducting the oil to the bearings resulted in the bearings heating until the rotors came into contact with the stators and produced faults in the windings. The motors have been strengthened and reconstructed in certain respects to ensure greater rigidity, and are now giving better satisfaction. The pinions now in use are of chrom-nickel steel, lubricated with a mixture of grease and graphite, and are wearing satisfactorily. It should be mentioned that the commutation of the motors is excellent and that the brush consumption is comparable with standard direct-current practice. No exact measurements of current consumption have as yet been made, but meter readings for a month's working show the consumption to be in the neighbourhood of 145 watt-hours per ton-mile on the three-phase side of the substations, or about 70 watt-hours per ton-mile at the single-phase side.

Some slight troubles were at first experienced with the overhead equipment, but these have now been overcome. The disc-type strain insulators, which were strung up with solid steel wire, broke frequently until stranded flexible steel cable was substituted. The iron-capped insulators at the pull-offs, &c., also broke frequently, and it was found necessary to replace these entirely with insulators of a different design, as the breakages were due to the difference in expansion between the insulator body and the iron cap cemented over it. The railway runs through a valley subject to severe wind-storms, and the climate is very severe, there often being several feet of snow and considerable variation of temperature, so that the present satisfactory state of the overhead equipment is very gratifying, considering its comparative lightness and low cost of construction.

**Shooting Match.**—On Thursday last the Siemens Dalston Works' Miniature Rifle Club tried conclusions with the Poplar Electricity Works' team, who are members of the Electrical League, the result being a win for the Siemens team. The average score of the "Drawn Wires" was 95·5 out of a possible 100. Mr. Horace Bowden opened the shoot for Poplar, and secured several bulls, which he evidently preferred to "Point Fives."

**Fire at G.E.C. Witton Works.**—A fire broke out last week in one of the various pattern stores adjoining the foundry of the works of the General Electric Co. at Witton. Although these stores were burnt down, none of the separate factories for the manufacture of all electrical plant, including carbons, conduits, small motors, switchgear, arc lamps, &c., were in any way affected. We also understand that the company's manufacturing arrangements are in no way interfered with, and that the factories are proceeding with work as usual. No inconvenience will therefore be caused to customers.

## A LOOSE HANDLE OIL IMMERSED STAR DELTA STARTER

A NEW design of star-delta starter has been placed on the market by the British Westinghouse Electric & Manufacturing Co., Ltd. (Trafford Park, Manchester), embodying some interesting features and advantages in its construction. The internal parts are mounted in a cast-iron frame with a cover having a suitable vent for gases. The oil-tank is below, forming the lower half of the starter, and can easily be lowered away when necessary. The contact drum is made on the metal and mica principle, and consists of a mica-insulated square steel shaft, on which are securely clamped spider castings carrying renewable segmental copper contact strips. The contact fingers are of the same type as those employed in standard Westinghouse controllers. Each finger has a large, cheaply and easily renewable arcing tip for taking all spark wear. All circuits are broken under oil. Adjustable phosphor-bronze springs are fitted to each individual finger, giving good constant and firm pressure. The no-volt and overload releases are fitted in the starter above the oil tank. The no-volt coil is connected across one phase, and is so arranged that the circuit to the motor can only be closed when there is voltage on the line. This release is worked by gravity, and acts quite independently of the overload

OIL-IMMERSED LOOSE-HANDLE STAR-DELTA STARTER.

release. The overload coil is connected in two phases, and is cut out in the star position, and can be set between approximately full-load current to 100 per cent. overload. The setting is effected by means of a screw on the top of the coil.

The operating handle is of the "loose" crank handle type, and the mechanical operation from the off to the star position and thence to the delta position is so designed with interlocks that the starter can be operated in no other way. A device is fitted making a slight pause necessary at the star position before it is possible to move the handle through to the delta position. The handle cannot be left in the star position, since, when it is released, it flies back to the off. The contact drum is returned to the off position (thus stopping the motor) in the event of an overload or failure of voltage, and cannot be held either in the star or delta position in such a case. A trigger release is also conveniently provided on the outside of the case. Ammeters can be mounted on these starters when desired, the instruments being of the moving-iron type, and are not in circuit when the drum is in the star position. Trifurcating boxes can be fitted if required, in which case the starter fully conforms with the new Mining Rules. Finally, following the well-known Westinghouse control-gear practice, this new starter is constructed on the metal and mica principle throughout.

## THE BALCKE WET AIR FILTER

SINCE the discussion on the subject at the I.M.E.A. Smeeing, considerable interest has centred around filtration and cleansing of the air supplied for cooling turbo-generators, and the advantages of washing the air rather than passing it through cloth are pretty generally admitted. We give here an illustration of the wet-air filter which has been designed for the purpose by Balcke & Co. (Broadway Court, Westminster) from experience with similar apparatus used

in connection with the ventilation of large buildings. The filter casing is of galvanised sheet-steel, the lower portion forming a water tank and the upper portion the filter proper, each being provided with facings for the water inlet and outlet connections. The air inlet is closed with wire-netted doors, which could, if required, be replaced by louvred doors. Immediately behind them a system of sprayers is arranged, which breaks up the water into fine spray, and thoroughly atomises it. The air is thereby brought into intimate contact with the water, so that the impurities are thoroughly moistened, and either fall by gravity into the tank, or are separated from the air by the baffle plates. The atomised spray is thrown in the direction of the air flow so that, instead of presenting a resistance to the air, as in the case of filters where the direction of the spray is opposed to the air flow, they will assist the flow of the air, thereby reducing the labour thrown on the fan and generator. The nozzles are made of gun-metal, and are of such construction that they cannot easily choke; the piping of the sprayers is all galvanised. The same water is used over and over again, being circulated by means of a motor-driven centrifugal pump.

To dry the air thoroughly, and to retain any impurities

SECTIONAL ELEVATION AND PLAN OF BALCKE WET AIR FILTER.

carried by the spray, a system of baffle plates is arranged at the air outlet of the filter, consisting of galvanised sheet metal strips, arranged at 45° to the longitudinal centre line of the filter; alternate rows being inclined in opposite directions. Each baffle is provided with an upright channel at the outlet edge, into which the particles of moisture and impurities are thrown and drained to the bottom of the filter, preventing any deposit being carried through from one row of baffles to the next. At the upper end of the spraying system a few special nozzles are arranged to throw water on to the top of the first row of baffles to assist in washing down any impurities retained. The tank at the air outlet end of the filter is provided with a large wash-out connection with overflow, with suitable valve leading into one common drain pipe, as at this end most of the impurities will settle. The pump suction is arranged at the opposite (the air inlet) end, separated from the main tank by a sloping partition protected with a removable cover. The flow of water towards this suction is exceedingly small, so that all the impurities, with the exception of the most minute, will settle in the bottom of the tank without getting to the suction chamber. The tank is provided with a make-up water-ball cock and separate connection for quickly filling the tank after it has been washed out, from the same source: one three-way cock operates the two inlets. A further connection is made from this make-up water pipe to the inlet end of the filter, to which a short piece of hose-pipe can be connected to wash out the tank when it is being periodically cleaned.

## PROPOSED EXTENSIONS AT THE BRADFORD ELECTRICITY WORKS

THE City Council of the Bradford Corporation has just approved and adopted a report by Mr. T. Roles (City Electrical Engineer and Manager), in which he points out the advisability for the immediate installation of a further 3,000-kw. turbo-alternator, converting plant, and a large storage battery, with the requisite accessories. It may be recollected that the present capacity of the generating station at Valley Road (*ELECTRICAL ENGINEERING*, Vol. VIII., p. 555, Oct. 10th, 1912) is about 15,800 kw., made up of twelve small D.C. sets aggregating 2,800 kw., four slow-speed D.C. sets of 1,000 kw., each making 4,000 kw., and three 3,000-kw. turbo-alternators making 9,000 kw. Owing to the very rapid increase in the demand for electric power, especially for textile mill driving by polyphase motors, it is estimated that the maximum load for the winter of 1913-14 will be not less than 11,500 kw., rising to 13,500 kw. in 1915-16, and as each turbo-alternator accounts for 20 per cent. of the works capacity, the margin of spare plant is very small. Mr. Roles suggests that the best course to pursue would be to instal a 3,000-kw. turbo-alternator complete with exciter and condensing plant at an estimated cost of £10,000 as soon as delivery can be effected, which is in about eighteen months from this time. He would wait two or three years before installing another turbo-generator, as he anticipates that prices will be closer when more experience has been obtained with 50-cycle machines up to 6,000-kw. run at 3,000 r.p.m. He also advocates the installation of two cooling towers and complete induced draught plant for the twelve boilers already in use, so that they can be forced, if necessary, and kept steaming at their maximum efficiency, as the existing arrangements are not always satisfactory in this respect. Two additional 1,500-kw. rotary-converters and switchgear at about £14,110, and a storage battery capable of discharging 5,000 amperes for one hour at about £16,756 are also contemplated. This battery would serve instead of an extra rotary-converter as a standby, as well as taking up the extra load occasioned by a storm in summer, or to take the load while extra boilers were got under steam when a prolonged abnormal load was coming on; while continuity of supply would be furthered. By the abolition of the small steam sets, ample space would be available for this battery.

The total cost of the extensions is estimated at £86,250, in which is included a sum of over £2,000 for suction ash handling plant to supersede the present somewhat primitive arrangements.

In order to provide for the ultimate use of the Valley Road Works as a sub-station, it is proposed that all additions to the generating plant be made in the engine-room, where the existing Curtis turbo-alternators are installed. To make room for the additional plant the 1,000-kw. slow-speed sets would be removed as necessary. All the obsolete small sets in the other part of the generating station could then be got rid of, and the space so set free used for extensions of the converting machinery and switchgear, &c., still leaving the large space for coal storage untouched. It will probably not be necessary to erect a new generating station for at least ten years, and it is unlikely that a suitable site could be found within four miles of the City; nor is it economically sound to erect a new generating station at the present time, because (1) the present plant capacity would not suffice during the time necessary for construction, and (2) the increased economies resulting would not nearly compensate for the additional financial burden. Mr. Roles further suggests the creation of a substantial reserve fund—10 per cent. of the capital expended is allowed by the provisional order—as a considerably reduced net profit for a number of years after the new plant is put into operation is to be expected.

**The Magnet Magazine.**—The current number of this interesting General Electric Co. publication puts on record the pleasant features of the famous "At Home" which the company gave last March at Covent Garden Theatre, and reproduces some representative photographs from the excellent series of films that were shown. There are also technical articles on electric labour-saving devices, and practical hints for motor attendants. The latest special pattern of carbon for cinematograph arcs made at Witton is described, and an article is given dealing with the Weichert electrolytic pleading apparatus. Mr. Barclay Gammon's clever G.E.C. alphabet is published, and the doings both of the firm and many persons connected therewith are chronicled and illustrated in an attractive way.

## I.E.E. STUDENTS' TOUR, 1913

AFTER several years of tours abroad, it was decided this year to hold the annual students' tour of the Institution of Electrical Engineers in this country, and Newcastle, the home of the most recently formed students' section, was selected. The party left London on Thursday, July 3rd, by the night train, arriving with the early dawn in Newcastle. The first visit was made the same morning to the Elswick works of Armstrong, Whitworth & Co., Ltd., where much of interest in the ordnance and electrical departments was seen. The electrical shop is devoted mainly to small work. Amongst other things were noticed a pistol-like switch for firing guns, and a neat little device whereby firing practice can be obtained with a stationary gun. A diagram of a ship is carried up and down a varying distance, and the closing of the firing switch causes a small pin to be projected to mark the diagram at the place the shot would hit. In the afternoon a visit was made to the works of A. Reyrolle & Co., Ltd., of Hebburn-on-Tyne, where their distinctive type of switchgear was seen in all stages of manufacture and completion. The method of assembling many of the parts on a jig, then turning the jig upside down and assembling another lot on it is ingenious and economical. An explosion-proof box, with the now well-known rough machined flanges, was arranged for demonstration. A high-pressure testing set was next exhibited, working up to 100,000 volts, together with its safety switches. Another interesting feature was the starting rheostats, where the elements are made up of metal and compressed carbon powder. The latter, having a negative temperature-coefficient, allows the current to grow at a steady predetermined rate, and prevents any excessive rushes. The visitors were hospitably entertained at tea by Mr. H. W. Clothier, who is the Honorary Secretary of the Newcastle Section, and several of his staff.

Next morning saw the party early astir to visit the turbine works of C. A. Parsons & Co., Ltd., at Heaton. Here the outstanding object was the 25,000-kw. set for Chicago, and the machines ranged downward in size from this to a 15-kw. set. The rolling of the blades to their finished section in long strips was interesting, and the skill exhibited in the hand-work of straightening the strips was striking. Two or three taps and it was done. A cable-making machine which wound the wires into a flat strip was also seen here. It was of the same general type as the ordinary machine, but was provided with a flat blade as the core-piece, off which the finished cable was drawn. This arrangement obviates the flattening of the cable to fit it into the slots, thereby preventing damage to the insulation. In the afternoon, Harton Colliery, which has a completely electrical equipment, was visited. Mr. Georgi, the consulting engineer, conducted the party around the gear at the pit head. The supply is taken from "The" Power Co. (there is only one in that part of the world) at 5,700 volts direct to the winding motors, the most noticeable of these being the large Siemens motor at the New Pit. The working face is two miles from the shaft. The loaded trucks from the various parts of the mine all come together at a large junction, and all underground haulage is by cable and electric motor.

Next morning the party visited the generating station at Carville. Of particular interest was the control room, where the whole system is laid out diagrammatically, and indicators are provided showing how all the feeders, switches, &c., are connected up, whether alive, and so on. This provides for the complete control of the whole system, extending over 1,400 sq. miles, being in the hands of one man. In the afternoon the Newcastle Section had arranged for a sail down the River Tyne to Tynemouth, where a brief visit was made to the lighthouse. Here vaporised oil and mantles to the tune of 1,000 c.p. hold sway, with a 200-c.p. electric lamp as stand-by and oil lamps as a further stand-by. An electric motor, however, is normally used to compress the air for the foghorn and oil feed, there being an oil engine as stand-by. After tea there followed a smoking concert, and the official visit ended, but on Sunday morning a visit was arranged by Mr. Cusworth, of Carville, to the Dunston Power Station (*ELECTRICAL ENGINEERING*, Vol. VII., p. 395, July 13th, 1911). In the yard were seen some under-running live-rail shields on test, ultimately destined for South America, and so the tour was finished.

The welcome and assistance given by the local section, especially by Mr. Henniker, the Hon. Sec. of the Newcastle Students' Section, were thoroughly appreciated, and it is believed that the system of visiting a local section, or for visiting London, for that matter, is well worth continuing.

## THE LIGHTING OF A CINEMA THEATRE

THE lighting of the Cinema House, Sheffield, represents a combination of several different systems. The scheme was prepared by the Illuminating Engineers of the British Thomson-Houston Co., Ltd., along lines suggested by Mr. Ravenscroft, the Managing Director of the theatre. The B.T.-H. Co. also supplied the Mazda drawn-wire lamps, fittings and other lighting equipment.

The chief considerations were that the lighting should be comfortable and restful, and should at the same time show up the decorative details of the interior. The auditorium is lighted by trough reflectors containing Mazdalite tubular lamps concealed in the cornice. The light is projected on to the curved ceiling, and from there reflected downwards into the auditorium. This cornice lighting is supplemented in a rather novel way. There are six domes in the roof of the auditorium, and each of these domes is covered on the under side by beautifully tinted amber glass. Above the glass around the bottom edge of each dome is arranged a row of upturned

AUDITORIUM WITH CONCEALED LIGHTING.

Mazdalux reflectors containing Mazda drawn-wire lamps, and the light is first projected on to the white dome, and a mellow radiance proceeds downwards into the auditorium via the stained glass. The illustration gives an idea of the excellent effect produced. The foyer and entrance are illuminated by "eye-rest" indirect and Alba semi-indirect fittings, while in the tea-room, B.T.-H. Holophane reflector bowls are used, supplemented by wall brackets.

## CATALOGUES, PAMPHLETS, &c., RECEIVED

**SWITCHGEAR.**—Substantial interlocked ironclad switch units for pressures up to 6,000 volts have recently been designed by J. H. Holmes & Co. (Newcastle-on-Tyne) for colliery and factory work. They are described in a new leaflet, which shows that the switchgear is of the carriage type travelling on steel channelways, so that isolating may be rapidly carried out. Another leaflet from the same firm brings to notice a design for remote operated clapper switches, which may conveniently be used in automatic starting on control gears for compressor or printing machinery, &c. The switches have auxiliary carbon contacts and magnetic blow-out coils.

*Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."*

**WIRELESS RECEIVERS.**—A folder from the Eclipse Electric Co. (6 Cambridge Road, Great Crosby) illustrates "Sterling" receiving head sets for wireless.

## CONDUIT SPACING SADDLES

SIMPLEX CONDUITS, LTD. (116 Charing Cross Road, S.W.C.) are introducing some new forms of "spacing saddles," which are the subject of a supplementary leaflet just received. These improved forms of holdfasts have been

NEW PATTERNS OF CONDUIT SPACING SADDLES.

designed for use where the conduit is installed on the surface, such as in damp situations, &c. They are so constructed that the conduit is installed with the clearance from the wall, thereby guarding the conduit against the effect of surface moisture or sweating. They are made in two forms. One pattern (illustrated on the right) is so constructed that the tube is simply dropped in position. It is made in two sizes, to take exactly the size of the tube which is being used.

There is also an improved pattern (illustrated on the left) in which the conduit is firmly held, as the fitting is made in two halves held together by means of two brass screws. The ordinary wood screws may be used for fixing, and considerable saving in labour effected by screwing direct between the bricks, although the wall should preferably be first plugged. They will be found quite the best type of holdfast for conduit installations in works, &c., where there is considerable moisture present.

## REVIEWS OF BOOKS

**The Year-Book of Wireless Telegraphy and Telephony, 1913.** 563 pp. 8½ in. by 5½ in.; about 46 figures. Portraits and Map. (London: St. Catherine Press.) 2s. 6d. net; by post, 2s. 11d.; abroad, 3s. 4d.

This useful handbook contains much information on wireless telegraph matters which has hitherto only been obtainable from scattered sources, and its completeness reflects great credit on the Marconi Press Agency, by whom it was drawn up. After calendars and a short record of the history of wireless telegraphy, the International Convention is set out in full, and the wireless telegraph laws and regulations of various countries are given, followed by lists of land and ship stations of the world, with their call signals. The more technical part of the book consists of the following series of articles:—Electric measurement in wireless telegraphy, by Prof. J. A. Fleming; Wireless time signals, by A. R. Hinks; The wireless direction finder, by C. E. Prince; Distress signalling, by G. E. Turnbull; The Marconi system of wireless telegraphy, by Andrew Gray; Principles of wireless telegraphy explained by mechanical analogies, by Capt. H. R. Sankey; Syntony, the technical situation in radiotelegraphy, by J. Erskine-Murray; The wireless telegraph receiver, by R. G. Kindersley; Wireless telegraphy for military purposes, by Major J. E. Cochrane; Facts and theories of long-distance signalling, by Dr. W. H. Eccles; and Methods of producing continuous waves, by C. E. Prince. There is also a useful glossary of terms and a quantity of general data relating to all parts of the world. A list of wireless patents also appears, particulars are given of the various associated Marconi companies, and there are biographical notes of some of the leading men connected with the movement. A list of books on the subject is also included, and after one or two other articles the volume concludes with a large map showing the principal wireless stations of the world open to public correspondence.

**Logarithms for Beginners.** By C. N. Pickworth. 49 pp. 7½ in. by 4½ in. (Manchester: Emmott and Co., Ltd.) 4th edition. 1s. net; by post, 1s. 2d.

This clearly written little manual on the use of logarithms has now reached its fourth edition, and in addition to the tables of four-figure common logarithms and antilogarithms, now contains a table of hyperbolic logarithms. The explanations are sound and straightforward, and are illustrated by plenty of examples.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,349.

State the theory of and advantages derived by using a loose-coupled inductance in wireless telegraphic receiving apparatus. Give the outline of construction of a suitable loose-coupled inductance for such work. Why is the iron core omitted in these, seeing that the two windings are quite independent, and apparently depend on transformer action.—F.

(Replies must be received not later than first post, Aug. 7th.)

### ANSWER TO No. 1,347.

In a 2,000-volt A.C. generating station of 3,000-kw. plant capacity (2 units of 1,000 kw., 1 unit of 500 kw., and 2 units of 250 kw.), a 1,000-kw. set and a 500-kw. set are running at nearly full load about 2 hours before peak time. The peak load expected is 2,500 kw. The ammeters on one of the feeder panels and on the panel of the 1,000-kw. set suddenly go hard over, and the switches on these two panels trip. State, in chronological sequence, what you would do if you were in charge at the time.

The first award (10s.) is made to E. C. PINCOTT, for the following reply:—

Exactly what to do in such a case of course depends very largely upon the circumstances under which the station is running at the time in question, viz., with regard to the load on the different feeders, &c., but as very little detail is supplied, the circumstances under which the station is running can only be assumed. In all probability the cause of the feeder switch tripping and also bringing out the 1,000-kw. set is a temporary short or complete breakdown of feeder. In any case it seems very strange that the 500-kw. set should remain in when the 1,000-kw. set came out, if all the protective gear was in order, unless the regulation was so bad at the time that this set could take a larger portion of the momentary heavy overload before tripping than the larger set, and it must be carrying a heavy overload.

Proceed as follows:—

Leave the feeder alone for the present. If the 1,000-kw. set is still showing about the correct pressure on the machine voltmeter, a hurried inspection will reveal whether it is all right or not.

If everything appears in order on this set, and having signalled the driver to "stand-by," proceed to synchronise it on to the bars to pick up the load. If, on the other hand, this machine (a) appears out of order, have the other 1,000-kw. set (b) run up as quickly as permissible, and put it on load. This 1,000-kw. set (b) should already be warmed up and ready for running, as in the ordinary course of events it would be required on load in about an hour's time. Of course, if any serious mechanical or electrical defect is detected in 1,000 kw. (a), it should be shut down immediately.

When a set has been got on load again, and up to that time no message has been received giving cause of the feeder tripping, close the feeder switch, but trip out if an abnormal current is picked up. Or better still, if the board has a set of duplicate bus-bars, arrange to isolate this feeder on a 250-kw. set to ascertain that the feeder is O.K., thus avoiding the risk of another disturbance of the supply if anything should be wrong with the feeder. If in case (b) feeder is O.K., if possible couple up the two sets of bars and shut down the 250-kw. set.

The second award (5s.) is given to E. H., who writes as follows:—

It is very difficult to say what one would have actually done under the circumstances related in the question. However, should he have kept a cool head, the following is the manner in which the writer would have proceeded. The switches on the alternator panel would be opened, its circuit-breaker put in, and the machine synchronised as quickly as possible. The act of synchronising with the breaker in affords sufficient protection should a fault have developed in the alternator either before or at the instant the breaker opened. Should this be the case, the breaker will come out a second time, probably bringing out the breaker of the 500-kw. set at the same time. The latter machine would then be switched back immediately, and the other 1,000-kw. set run up and synchronised without further loss of time. During these few minutes the 500-kw. alternator would probably have to be doing about 100 per cent. overload, which it ought to be able to cope with for that short interval of time.

In the meantime, however, the switches on the feeder panel affected should be kept open, as it is evident that the trouble must have originated on this, and switching this feeder on to the 500-kw. set would in all probability shut down the station temporarily.

However, since both feeder and machine breakers came out, it seems almost certain that the alternator is sound, and that its breaker merely tripped because the heavy current taken by the feeder was chiefly supplied by the bigger set on account of its superior regulation, as they were already running at nearly full load. Hence, after synchronising, the next thing would have been to open the switches on the feeder panel affected, close the circuit-breaker and then the switches. If this brings out the breaker again, wait for an interval of about a minute, and try switching the feeder on a second time. Should this fail, then the best thing is to ring up the main's engineer to investigate the cause of the trouble. It is quite possible that the short or earth on the feeder was only temporary, and would have been cleared by the time the feeder was switched on. In that case, nothing further would have to be done.

After proceeding so far, one could start thinking of how to face the peak-load. Should the first 1,000-kw. set have proved sound, all well and good; but there is the possibility of a fault having developed sufficient to put the machine out of commission, then the writer would have risked the 25 per cent. overload on the remaining alternators (assuming that the faulty feeder had by this time been put right), if the overload would not last for more than an hour; otherwise the only thing to do would be to request some of the customers to take off their loads during the peak.

### ANSWER TO CORRESPONDENT

**ACCUMULATOR.**—It is certainly possible to discharge the battery in question through an artificial load consisting of a water resistance, but we do not quite see your object in so doing.

**The Batti-Wallahs.**—Mr. Riggs (Past President) has again kindly placed at the disposal of the Society his sailing barge *Alda* from August 1st to August 11th. Comfortable cabin beds are provided, and this year, in addition to the advantages of electric light, a complete range of electric cooking apparatus has been installed. A number of members have signified their intention of joining the outing, but there are still vacancies. The number is limited to 16, and those who are desirous of joining the party should apply at once. Members can come for the whole of the time, or for one or two week-ends, namely, August 1st to 4th, or from August 8th to 11th. The inclusive cost of the trip will not exceed £3 10s. or 45s. for the week-end.

# "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

## Specifications Published July 24th, 1913

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

7,651/12. **Rotary Converters.** E. C. Co. and N. PENSABENE. Each pole consists of a group of polar projections, and the armature is wound with at least two separate windings arranged for different numbers of poles. An adjustable iron core between adjacent polar projections in the same group enables a leakage flux to induce a back E.M.F. in the winding for the larger number of poles, and a direct E.M.F. in the others. Two figures.

15,279/12. **Incandescent Lamp Filament Supports.** JULIUS PINTSCH A.-G. To mount the filaments rapidly and accurately, the supporting arms are arranged in pairs in two tiers so that each arm of each pair is at an angle to the plane of the complementary arm. Five figures.

15,486/12. **Railway Signalling.** R. H. STOCKDALE. A lock and block system for single-line working is described. A single needle instrument is used in conjunction with electro-mechanical locks in the signal box and on the signal posts. On failure of the batteries no "clear" signal can be given. Four figures.

23,453/12. **Incandescent Lamps.** T. F. J. TRUSS. A prismatic reflector on the central stem is made hollow with its inner surface reflecting, and is provided with longitudinal prismatic ribs which have their apices projecting between the filaments. Two figures.

24,361/12. **Incandescent Lamps.** W. L. PAKENHAM ("Z" Lamp Manufacturing Co.) Phosphor is painted on the stem of drawn-wire lamps to prevent blackening.

530/13. **Control of Heating Apparatus.** G. SMITH. Circuits are arranged so that when started a liquid is boiled and a predetermined quantity poured into an adjacent receptacle. This operation opens the main circuit and closes an alarm circuit. Four figures.

8,027/13. **Current Transformers for High Pressure.** SIEMENS BROS. (*Siemens & Halske*). The iron cores are arranged with their respective secondaries upon a common co-axial insulated primary winding. Two figures.

## Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

**Arc Lamps:** HERWIG [Electrodes and holders] 15,927/12.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** BECKER [Reducing energy loss in variable current lines] 27,535/12; FORSTER [Pole caps and insular supports] 10,085/13.

**Dynamos and Motors:** LUNGSTROM [Rotating field magnet windings] 24,484/12.

**Electrometallurgy and Electrochemistry:** STOBIE [Improving physical nature of pig-iron] 16,001/12; SCOTT [Nitrogen fixation furnace] 16,014/12; LEE and BRAINE [Anodes for electrolytic apparatus] 16,475/12; MICHAUD and DELASSON [Recovery and refining of tin] 20,557/12; NODON [Cold electrolytic process for the recovery of tin from waste tinned metals and alloys] 24,203/12; ALLEN and ALLEN [Electrolytic cells] 26,169/12.

**Heating and Cooking:** GRUNDY [Heaters] 18,017/12.

**Ignition:** NEHMER, 18,799/12.

**Incandescent Lamps:** CERVENKA [Repairing] 16,885/12; GODIN [Lamps for automobiles] 29,149/12.

**Storage Batteries:** CLARK and HART ACCUMULATOR Co. [Portable] 2,908/13.

**Switchgear, Fuses, and Fittings:** PRIM and ROPER [Thermostats] 16,317/12; ELLISON and MUELLER [Motor controllers] 22,959/12; GORTON [Automatic S.P. switch] 608/13; WHIPP, BOURNE and WHIPP [Remote-controlled circuit-breaker] 2,233/13; SIEMENS-SCHUCKERT [Lamp and fuse-plug sockets] 5,903/13; UNITED MOTOR INDUSTRIES and DE RODAKOWSKI [Bayonet-socket holders] 7,477/13.

**Telephony and Telegraphy:** DUBILIER [High-frequency currents] 8,197/12; PLECHER [Telephone receivers] 13,157/12; W.E. Co. (*W. E. Co., U.S.A.*) [Telephone machine switching] 15,952/12; 12,425/13; 12,424/13; 12,425/13; and 12,426/13; CONNER [Telephone indicator] 23,812/12; SIGNAL GES. [Leakage telephony and telegraphy] 3,853/13.

**Traction:** LEKKERKERKER and BECKX [Drawing-up and securing broken ends of trolley wires, &c.] 9,547/13.

**Miscellaneous:** DAMEY, ESCORÉ and ESCORÉ [Imitation candle lamps] 15,456/13; HUNTE [Battery lamps] 16,126/12; B.T.-H. Co. (*G. E. Co., U.S.A.*) [Vapour electric devices] 18,372/12; EREDE [Gyroscopically-controlled cabin for ships] 20,985/12;

BURBURY, HILLIER and THOMPSON [Packing incandescent lamps] 24,596/12; LILIENTHAL [Röntgen rays] 1,843/13.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** DATTA [Covering conductors] 1,343/13; FRANZ [Series-connected apparatus] 15,502/13.

**Telephony:** TELEPHON APPARAT FABRIK E. ZWIETUSCH [Exchanges] 14,229/13; REEVES [Automatic exchanges] 15,579/13.

**Traction:** PIEPER [Vehicle driving] 15,138/13.

**Miscellaneous:** GRAEMIGER [Suspension devices] 24,541/12; CAHUCITWERKE NÜRNBERG [Blasting machine] 14,870/13.

The following Amended Specification may now be obtained.

3,549/12. VAN RADEN & Co., and M. METZ [Multiple-circuit distributing switch for motor-car circuits].

## Applications for Amendment

8,853/11. **Frequency Changing.** A. M. TAYLOR. The patentee wishes to amend this specification (*ELECTRICAL ENGINEERING*, Vol. VIII., p. 448, August 8th, 1912), as part of claim 1 is incorrect, and there is an ambiguity in claim 6.

11,871/12. **Automatic Regulator for Variable Speed Dynamos.** H. D. EARL. A shunt field regulator controlled by a series and a shunt coil is described. The resistance between the regulator contacts gradually alters as they are separated, and the controlling windings are so proportioned that the shunt winding is operative independently of the current in the series coil. Application is being made by J. Stone & Co. to correct certain clerical errors in the specification, and to more clearly define the scope of the invention. It is proposed to describe more fully the regulator, which consists of successive pairs of contacts whose resistance varies directly as the pressure applied. They open successively. Claims 1, 2, and 3 are to be struck out, and a new claim substituted.

## Amendments Made and Allowed

1,950/08. **Telephone Switch Hooks.** J. E. KINGSBURY (*Bell Telephone Mfg. Co., Antwerp*). Some of the desired amendments (*ELECTRICAL ENGINEERING*, May 29th, p. 310) have been allowed.

## Grant of Patents Allowed

27,521/11 and 28,260/12. **Cinematograph Targets.** J. B. LE MAITRE. The opposition to the grant of these patents (*ELECTRICAL ENGINEERING*, March 6th, p. 136, and March 20th, p. 166) has resulted in the Comptroller requiring some amendments to be made.

## Grant of Patent Refused

19,890/12. **Self-contained Vehicles.** OERLIKON Co. The opposition to the grant on this application (*ELECTRICAL ENGINEERING*, July 24th, p. 432) by Mr. W. P. Durnall has resulted in the grant being refused. Mr. Durnall was also allowed £3 3s. costs.

## Expiring and Expired Patents

The following Patent expires during the current week, after a life of fourteen years:—

16,005 of August 5th, 1899. **Incandescent Lamp Manufacture.** A. SWAN. The stem is fused to the inner wall of the neck of the lamp, and simultaneously definite shape is given to the neck by air pressure, so that it accurately fits the lamp cap, to which it is at the same time secured.

The following are the more important Patents that have become void through non-payment of renewal fees.

**Distributing Systems, &c.:** M. BÜTTNER [Train-lighting system in which aluminium cells and iron regulating resistances are used] 8,121/02; B. T.-H. Co. (*G. E. Co., U.S.A.*) [Control system for two motors running at different speeds] 8,153/07.

**Electrochemistry and Electrometallurgy:** H. M. GRANIER [Production of caustic alkali, copper sulphate, &c., by electrolysis] 4,487/04; A. M. DOUILLET [Water sterilising by electrolysis] 8,332/06 and 14,248/08.

**Ignition:** H. HOLZWARTH and E. JUNGHAUS [Gas turbine] 8,578/07.

**Instruments:** C. E. FOSTER ["Null" galvanometers] 8,205/07.

**Miscellaneous:** P. M. JUSTICE (*Rowland Teleg. Co., U.S.A.*) [Maintaining synchronous rotation of a motor and a shaft by periodically varying the duration of a shunt across its field or armature] 8,488/02; E. ALBERT [Electrotypes] 8,117/04; D. K. MORRIS and G. A. LISTER [Eddy current brake] 7,448/05; T. L. JONES and AUTO-ELECTRIC RIFLE AND TARGET Co. [Target practice] 7,755/05; A. J. BOULT (*Goldman and Co., U.S.A.*) [Pasteurising] 8,084/08; W. J. BRENNAN [Waxing thread] 20,356/08.

## TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

Following on the letter by Sir Joseph Larmor, in which he urged the necessity of the State seeking and using the best scientific knowledge in the country bearing on the Imperial wireless scheme, the Postmaster-General has announced that, on the advice of the Advisory Committee and others, Mr. W. Duddell has been retained for a number of years in this connection. Mr. Duddell will be in touch with the leading experts in wireless telegraphy from the various Government departments, and when occasions arise it is intended that advisory committees similar to the one recently formed shall be invited to consider particular aspects of the problem. The Postmaster-General also stated in the House of Commons on Monday that the terms of the Marconi contract had been modified to the advantage of the Government. The new contract provided for the payment of royalties in respect of each station, and not of the Chain as a whole. The Company had agreed to this, but later they found that they are not protected by patents in British East Africa, where the largest of the stations is to be situated. In return for royalty payments being made in connection with this station, the Marconi Co. have agreed to the 10 per cent. royalty payable for each station being subdivided thus:—4 per cent. in respect of internal transmitting apparatus, 2 per cent. in respect of internal receiving apparatus, and 2 per cent. each in respect of external transmitting and receiving apparatus. Thus full liberty is retained to discard Marconi apparatus in respect of one part of a station, while retaining it in the others, and securing a proportionate reduction in the royalty by so doing.

At a recent meeting of the Institute of Radio Engineers, held in New York, a Paper was presented by Mr. J. L. Hogan, jun. (National Electric Signalling Co.), in which the principle and apparatus involved in the heterodyne receiver, invented by Prof. R. A. Fessenden, and used for the long-distance communications in the recent wireless tests between Arlington and the *Salem*, were discussed. The heterodyne receiver is a selective receiver which will amplify persistent waves, but will not increase effects due to highly damped discharges, e.g., atmospherics. The author described five types of heterodyne receiver. In the first two, wave trains having slightly different frequencies are received on two separate antennae. The currents set up are passed through a non-polarised magnetic telephone, and react on the diaphragm. In the second, only one antenna is used, as the second of the interacting currents is produced by an alternator, arc or other oscillator. The third form has its sensitiveness increased by the use of a dynamometer telephone, and the fourth employs a static telephone receiver. With this arrangement signals are said to have been received up to 3,000 miles. In the fifth type heterodyne excitation is added to the modern combination of sensitive rectifier and telephone. In this case, receiving from sustained wave or spark transmitters, it is possible to read signals so weak that they cannot be heard in the ordinary receiver. On spark signals the improvement is from five to fifteen times, and with sustained waves is greater. This receiver was used for all the long-distance signal tests between Arlington and the *Salem*. Two stations of the Arlington type could, it is estimated, exchange messages regularly by day or night over 2,800 miles.

The French Post Office authorities are investigating a system of wireless telegraphy for long-distance transmission, invented by M. Bouthillon. According to the *Elektrotechnische Zeitschrift*, long waves several hundred kilometres in length, corresponding to a frequency of about 1,000 cycles per second, are employed. An antenna about sixty miles long, supplied from an ordinary alternator generating at the above frequency, is used, and at the receiving end no detector is required as the waves produce oscillations in the receiving circuit which

are audible in the telephone. A very high efficiency is claimed for the system.

According to the *Elektrotechnische Zeitschrift*, wireless telephony has been effected between the Nauen station, and several others, including one at Vienna, over distances of 400 miles and more. A "Telefunken" high-frequency machine was used at Nauen, and the conversation was received at Vienna loud, clear, and perfectly intelligible.

Wireless communication between St. Kilda and the mainland was established on Tuesday.

The Radiotelegraphic Convention, which came into force in the 1st inst., has so far been ratified by Belgium, Belgian Congo, Denmark, Egypt, United States of North America, Monaco, Holland, Curaçao, Netherland Indies, Russia, Portugal, Newfoundland and Great Britain.—Communication with all stations in Angola is restored.

## ELECTRIC TRACTION NOTES

The point which has been so long disputed between the Tottenham Urban District Council and the Metropolitan Electric Tramways, Ltd., as to whether certain tramways authorised under the Light Railways Act could come within the definition of a railway for the purposes of rating, i.e., should be rated upon one-fourth the assessment value, has been finally settled by the House of Lords. The local justices and subsequently the Divisional Court held that tramways so authorised did not come within the definition as contended by the Company, but the Court of Appeal subsequently gave a decision against this and in favour of the Company. The House of Lords, however, have reversed the decision of the Court of Appeal. In giving judgment, Lord Justice Moulton expressed the opinion that it was an abuse of the Light Railways Act of 1896 to make use of it for the purpose of constructing lines which were purely tramways, as distinct from light railways in agricultural districts, which was the main purport of the Act.

The electrification of the Butte, Anaconda & Pacific Railway is now practically complete. It is the first railway in America to adopt the high direct-current pressure of 2,400 volts. For both freight and passenger work the motors are wound for 1,200 volts and insulated for 2,400 volts; the gear reductions are 4.84 and 3.2. There are four motors per unit, and two units form one locomotive for freight work. Each unit weighs about 80 tons, and the two units will haul a 3,400-ton train at 21 m.p.h. on the level or 15 m.p.h. against the ruling grade of 0.3 per cent. Each motor is rated at 190 amperes at 1,200 volts under forced ventilation on continuous rating; thus, for the double unit the output is equivalent to about 2,100 h.p. The control is on the Sprague multiple-unit series-parallel system, and a dynamotor is employed to furnish 600 volts for the operation of the contactors, lights and air compressor. The resistance units number twenty and twenty-six for the passenger and freight locomotives respectively. The passenger locomotives have two pantograph trolley collectors, and each freight unit has one. Single units are used for making up trains and for spotting cars. The wheels have a diameter of 46 in.; the total wheel-base is 26 ft. and the rigid wheel-base only 8 ft. 8 in. The maximum tractive effort per locomotive, continuous rating, is about 11 tons., one hour rating about 13.5 tons, and 30 per cent. coefficient about 21 tons.

According to *Elektrotechnik und Maschinenbau*, a scheme has been prepared by M. Carlier for the electrification of the Brussels suburban railway system, including the underground connection through the city between the north and south stations, which would be the first section to be electrified. The high-tension direct-current system is proposed, with third-rail current collection at from 1,200 to 1,500 volts. Three-phase power would be supplied to substations at intervals of from six to eight miles, at 15,000 volts. Locomotives of from 1,500 to 2,000 h.p., capable of handling the heaviest

trains would be employed. It is also proposed to join the two main stations by a new loop-line, which would greatly increase the capacity of both by partly eliminating the terminal nature of the traffic.

According to the *Elektrotechnische Zeitschrift*, an order for 300 electrically-equipped motor-coaches for the St. Petersburg suburban railway system has been placed with the Russian Allgemeine Elektrizitäts Gesellschaft and Siemens & Halske conjointly. The new Russian Dynamo Co. has received an order for a further twenty coaches. No particulars of the equipments are yet to hand.

## LOCAL NOTES

**Bradford: Electricity Extensions.**—The large scheme of extensions to the electricity undertaking prepared by the City Electrical Engineer, Mr. T. Roles, and referred to at length on page 443, has been passed by the City Council.

**Chester: Electricity Output.**—The output of electrical energy during the past year exceeded that of the previous year by nearly a quarter million units. In spite of the price of coal having gone up considerably, the generating costs per unit have been reduced to 0.889d., which is less than in the previous twelve months.

**Edinburgh: Electric Lighting Profits.**—The Electric Lighting Committee has recommended that the surplus of £2,169 in hand upon the electricity undertaking should be devoted to the reduction of the capital account, and not to the relief of rates as is the opinion of a number of members of Council.

**Kingston-on-Thames: Electricity Accounts.**—The accounts of the electricity undertaking for the past year show a net loss of £1,255. This is mainly attributable to the increased cost of coal, which represented an additional outlay of £1,094 during the year. Public street lamps in the main roads have been changed from the open type of arc lamps to clusters of high power metal-filament lamps, and this change has brought about a marked improvement in the lighting. It has also enabled the shutting down of special high-tension continuous-current arc lighters at the power station, as the supply for the new clusters is taken from the low-tension distribution system. In spite of the unsatisfactory financial result, over which, as mentioned above, the Committee or the staff had very little control, the efficiency in the running of the undertaking has been increased as compared with previous years.

**London: L.C.C.: Protective Devices.**—Since the recent serious breakdown of plant at the Greenwich Power Station, consideration has been given by the Highways Committee to the question of arranging for the installation of protective devices with a view to guarding against breakdowns in the future, and localising them when they occur. The Chief Officer of Tramways, Mr. A. L. C. Fell, has conferred on the subject with Mr. G. W. Partridge, Chief Engineer to the London Electric Supply Corporation, and a scheme has been submitted, estimated to cost £25,000, for dealing with the two 8,000-kw. generators recently ordered from the British Westinghouse Co. This has been approved by the Highways Committee.

**Middlesbrough: Electric Lighting Tariff.**—Mr. H. M. Taylor, the Borough Electrical Engineer, has presented a report with regard to systems of charging for electricity supply. This report, which is to be printed and considered later, is, it is stated, against the adoption of the rateable value system.

**Nuneaton: New Plant.**—Reference was made in this column last week to a new turbo-generator which has lately been started up. The plant, however, was incorrectly described, and should be a 500-kw. Willans-Siemens mixed-pressure turbo-generator.

**Stoke-on-Trent: Electricity Accounts.**—The net profits upon the various power stations owned by the Corporation for the past year were as follows:—Burslem, £838; Hanley, £222; and Stoke, £299. On the Longton undertaking there was a loss of £141.

**West Ham: Electricity Accounts.**—The figures of the electricity undertaking for the past year show a steady advance in the number of units sold for private houses, shops, and particularly for factories. The report points out that, owing to recent improvements in lamps and fittings, and the increased attention which is being given to the question of good lighting and pure air in factories and workshops, this latter class of business is now comparatively easy to obtain.

With heating and cooking, also, there has been a considerable advance, which it is anticipated will be considerably improved upon next year in consequence of the new tariff recently passed by the Corporation. The net surplus for the year was £495, but in considering this, allowance must be made for the fact that extra charges in respect of coal amounting to £1,400 had to be made, that there was a loss of £3,700 from the traction supply, owing to reduction in price, and that new meters to the value of £192 have been purchased out of revenue, and also an expenditure of £500 has been made out of revenue upon the enlargement of central office buildings, alterations to switchboard, cables, &c.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

### Generating Stations, Sub-Stations, Mains, &c.

**Bolton.**—The Local Government Board has sanctioned loans amounting to £26,897 in connection with a new power station at the Back-of-th'-Bank.

**Bury.**—Tenders are invited for a 2,000-kw. turbo-alternator with exciter and condenser. August 25th. (See advertisement on another page.)

Sanction to loans amounting to £55,000 for electrical extensions is to be sought.

**Doncaster.**—A loan of £12,500 for electrical extensions has been inquired into. These extensions are mostly in consequence of additions to the Corporation's limits of supply, and the development which is anticipated in the new colliery district of Brodsworth.

**Dublin.**—Tenders are invited for feed pump, pipework, steel-work, &c. August 26th. (See advertisement on another page.)

**Felixstowe.**—A Local Government Board inquiry is to be held regarding a loan of £4,729 for the electricity undertaking.

**London: Hammersmith.**—Tenders will shortly be invited for a twelve-months' supply of cables and high and low-tension switchgear.

**Long Eaton.**—A loan of £10,000 for electrical extensions has been inquired into, and the extensions include a 500-kw. generating set.

**Willesden.**—A Local Government Board inquiry is to be held regarding a loan of £4,667 for the electricity undertaking.

### Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

**Barnet.**—New infirmary.

**Barrow-in-Furness.**—New public baths (£15,900).

**Belfast.**—Cinematograph theatre, Falls Road. Architect, W. Y. Moore, 35 Royal Avenue.

**Cheltenham.**—New municipal offices (£9,500).

**Eastbourne.**—New workhouse buildings.

**Hull.**—Picture theatre.

**London: Greenwich.**—Elementary school, Charlton Road.

**Port Talbot.**—Offices, &c., for the Port Talbot Steel Co. Architect, G. Moxham, 18 Castle Street, Swansea.

**St. Marychurch (Torquay).**—Electric lighting is to be installed in the parish church.

**Stalham (Norwich).**—Enlargement of town hall.

**Sunderland.**—Extensions to the eye infirmary (£20,000).

### Miscellaneous

**Bradford.**—After having received reports upon electrical and gas lighting for street purposes, a Special Finance Committee has recommended the adoption of electricity for certain streets in the town.

**London: L.C.C.**—Tenders are invited for the provision of

FOR  
**STEAM JOINTS**  
USE

JOHN HUDSON & CO.'S SUCCESSORS, Mansell St., London, E.

testing plant for polyphase electricity meters. An offer by Dr. C. V. Drysdale to prepare the specification and superintend the installation of the plant for ten guineas, and make tests for a further ten guineas, has been accepted.

**Hammersmith.**—The Works Committee recommends that fifty existing gas lamps in side streets be converted to incandescent electric lighting.

**South Africa.**—A supply of 36,000 metal-filament lamps is required by the South African Railways Administration. Further particulars, 73 Basinghall Street, E.C.

### TENDERS RECEIVED AND ACCEPTED

**Belfast.**—The tender of Bertram Thomas for a switchboard panel has been accepted.

**Falkirk.**—The contract for A.C. meters has been given to Chamberlain & Hookham, Ltd.

**London: L.C.C.**—The following tenders have been received for the electric lighting of the new fire station at Hackney: G. E. Taylor & Co., £162; Tredegar & Co., £196; H. J. Cash, & Co., £238 7s.; Finch & Wheeler, £254 7s.; Cox-Walkers, £357. The first-named tender is recommended for acceptance.

The following tenders have been received for switchgear at the Shoreditch, Camberwell and Woolwich sub-stations, and the central car repair depot: Spagnoletti, Ltd., £999 14s.; Johnson & Phillips, £1,068; Ferranti, Ltd., £1,100 5s.; Switchgear & Cowans, £1,140 18s.; Eckstein, Heap & Co., £1,330 15s.; A. Reyrolle & Co., £1,387 11s. The tender of Messrs. Spagnoletti, Ltd., has been recommended for acceptance.

The Port of London Authority, which recently authorised an expenditure of £104,000 upon the electrical equipment of its docks, has received tenders for the supply to the Albert Docks of forty-three electric luffing cranes of 60 ft. radius, with a lifting capacity of 30 cwt. at ordinary speed, and 3 tons at a slower speed.

**Northwood.**—The tender of the Northwood Electric Light & Power Co. has been accepted for street lighting.

We learn from the British Thomson-Houston Co., Ltd. (Mazda House, 77 Upper Thames Street, E.C.), that the United States Government has issued instructions that Mazda lamps shall be exclusively used in future in all Government installations. The lamps have to pass stringent tests before acceptance, and conform to a strict specification.

### APPOINTMENTS AND PERSONAL NOTES

We learn that Mr. E. P. Barfield, who for the past six years has been Manager to Messrs. Siemens Bros. Dynamo Works, Ltd., incandescent lamp and fittings department, has accepted an important position with the Edison & Swan United Electric Light Co., Ltd., with whom he was connected at the outset of his career. We understand, however, that Mr. Barfield will not actually be leaving Dalston Works for some little time.

Acting under medical advice, Mr. Alfred Clough has resigned his position as Consulting Electrical Engineer to the Liverpool Corporation. The Electricity Committee has passed a resolution placing on record their appreciation of the services rendered by Mr. Clough in his past management of the electricity undertaking.

The Leicester Electric Lighting Committee recommend that the salary of the Chief Electrical Engineer, Mr. T. R. Smith, be increased from £600 to £900 per annum by annual increases of £100.

In consequence of Mr. R. N. Mayne being appointed Borough Electrical Engineer at Redditch, Mr. L. H. Saynor has been appointed Chief Assistant Electrical Engineer at Erith, at a salary of £160 per annum, rising to £200. An additional shift engineer is to be appointed.

Partner required for electrical contracting business in London. (See an advertisement on another page.)

An assistant electrical engineer is required by the Port Elizabeth (S.A.) Council. Salary, £500 per annum. Applications to Davis & Soper, 54 St. Mary Axe, London, E.C.

Plumber-jointers required by British Insulated & Helsby Cables, Ltd. (See an advertisement on another page.)

A Clerk of the Works to supervise the construction of a refuse destructor, generating plant, sub-station and laying of mains is required at Rhondda. (See advertisement on another page.)

### MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. George Smith & Son of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars c.i.f. port of arrival, quoted on Tuesday night, was £69 to £69 10s. (Last week, £66 5s. to £66 15s.)

**Works Holidays.**—The Electrical Power Storage Co., Ltd. (Millwall, E.), will be closing their works from Friday evening next to Monday morning, August 11th, but a small staff will be at the offices to deal with urgent correspondence.

The Union Electric Co., Ltd., will close their offices and stores on Monday and Tuesday next, and their works from Monday the 4th until Saturday the 9th, re-opening on Wednesday the 6th and Monday the 11th respectively.

**Annual Picnic.**—Some thirty members of the staff of the Synchronous Co. (32 and 34 Clerkenwell Road) made a launch excursion from Kingston to Windsor and back on July 19th.

**Electrical Novelties.**—We are asked by the General Electric Co., Ltd., to state that the new pocket lamp in the shape of a pistol, which we illustrated on page 492 of last week's ELECTRICAL ENGINEERING, is to be known under the trade name of the "Defiance."

**Liquidations.**—A meeting of the creditors of the Miners' Lamp Electric Lighting Co., Ltd., will be held at the office of the liquidator, James Blakey, 42 Spring Gardens, Manchester, on August 12th, at 12 noon.

### COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

**London Electric Supply Companies.**—The County of London Electric Supply Co. has announced an interim dividend of 5 per cent. per annum on the ordinary shares. A 5 per cent. interim dividend has also been declared on the ordinary shares of the West-End undertakings of the Charing Cross, West End & City Electricity Supply Co. £17,747 is carried forward. On the City undertaking £10,401 is carried forward after debenture interest, and preference dividends are provided for. A 4 per cent. interim dividend has been declared by the Metropolitan Electric Supply Co.

**Bombay Electric Supply.**—At the meeting recently a total increase of revenue of 13.28 per cent. was reported. After deducting debenture and preference interest, and placing £22,000 to depreciation, an available balance of £35,072 remained, including £7,385 brought forward from last year. A 5 per cent. dividend is to be paid, with £5,072 carried forward. The total energy supplied has increased by 30 per cent., but the generating costs show a decline due mainly to the better efficiency of the new Kussara station which replaces that at Wari Bunder.

**Brush Electrical Engineering Co.**—The accounts for 1912 show a deficit of £7,710. After paying debenture interest this increases the debit balance to £243,442.

### NEW COMPANIES

**HYDRAULIC POWER CO. OF SCANDINAVIA.**—Capital, £425,000. To acquire and work water-power concessions and adopt an agreement with the Hydraulic Power & Smelting Co. The first directors are R. Blakstad, S. Hultdt, A. List, E. Rael, and J. A. Stirling.

**SEVENOAKS & DISTRICT ELECTRICITY CO.**—Capital, £140,000. In order to meet the requests for an early supply, the directors are establishing a temporary generating station.

**CENTRAL ARGENTINE LIGHT & POWER CO.,** 3 London Wall Buildings, E.C. Capital, £100,000. To erect generating stations on the San Juan River and elsewhere.

## SUMMARY

THE annual report of the City Engineer to the Corporation of London contains notes on the street lighting in the City and other matters of interest. (Page 452.)

THE conversion of a mill in the Birmingham district where brass, copper, and white metal is rolled, to electric drive is described in an illustrated article. The space gained by the removal of the old steam plant has enabled a considerable amount of new machinery to be added to the mill. (Page 453.)

WE are able to give from notes sent us by a correspondent some particulars of a 4,800-kw. power transmission projected in connection with the Mount Lyell Mines, Tasmania. (Page 454.)

A MOTOR-DRIVEN centrifugal disintegrator for foundry sand is illustrated and described. (Page 455.)

THE patent specifications of particular interest to mining electrical engineers and electro-metallurgists published during the preceding month include some dealing with miners' safety lamps and electric furnaces

for the production of sulphur-free iron, and some covering electrolytic refining processes. (Page 456.)

A NEW design of commutating pole motor giving good ventilation and high efficiency has been introduced. (Page 456.)

DESIGNS for a solenoid-operated circuit breaker are given in our Questions and Answers columns. (Page 457.)

THE specifications published last Thursday include one for a water-cooled, three-phase furnace for fixing nitrogen, by E. Kilburn Scott; one for a construction of salient pole high-speed rotor, by F. Ljungström; and one dealing with the improvement of speech over long telephone lines by the use of shunts at intervals, by F. A. Becker. The patent for electric clocks, by T. J. Murday, which was allowed to lapse, has been restored. (Page 458.)

A CONVENIENT machine for crushing coal and taking samples for testing has been introduced. (Page 459.)

IN consequence of the decision in the Tottenham tramway rating case, the Accrington Corporation has had to refund certain sums deducted on the strength of the Appeal Court's judgment which has now been reversed.—Owing to the extraordinary diminution in receipts on the L.C.C. tramways in different parts of London, many Borough Councils have agreed to a re-valuation for rating purposes. The Islington Council, however, refused, but the High Courts have ordered a revaluation to be made in this case also.—Owing to the influx of water in the Loetschberg Tunnel the full service of electric trains has had to be postponed. (Page 459.)

WE refer to the latest edition of the Post Office Wireless Telegraph Handbook.—For the protection of wireless aeriads against lightning risks it has been suggested that a double pole, two-way switch should be used for earthing both the aerial and the metal guy ropes. (Page 459.)

INTERESTING revisions in tariffs for domestic supplies, other than lighting, have been made at Glasgow and Beckenham.—There was a net profit of £7,520 on the Glasgow electricity undertaking last year, after providing £50,000 for depreciation.—The Lytham Council is considering taking a supply in bulk instead of erecting its own power station.—A large electric supply scheme in Bavaria is referred to.—A curious position has arisen in regard to the Kingstown electric lighting Order, the Board of Trade having abandoned the Order owing to opposition in the House of Commons. The promoters, however, are taking steps in the matter. (Page 461.)

AN expenditure of £9,500 is contemplated at Limerick and £21,500 at Tauranga (N.Z.).—Switchgear

is required at Burton-on-Trent, and at Canberra (Australia).—Estimates are being prepared for mains and services extensions at Accrington, and electric lighting schemes are under consideration for Ballater, Lurgan, and Egypt. (Page 461.)

THE Brush Electrical Engineering Company's report for last year explains the deficit of £7,710 as being due to the coal and other strikes, the extra expenditure incurred by the Workmen's Compensation and the Health and Unemployment Insurance Acts, and the fact that many contracts completed during the year were undertaken when lower prices prevailed a few years ago against which the cost of materials has risen since. The scheme of capital reorganisation has been postponed until the publication of the current year's accounts. (Page 462.)

### STREET LIGHTING AND OVERHEAD WIRES IN THE CITY OF LONDON

THE annual report of the City Engineer, Mr. Frank Sumner, to the Improvements and Finance Committee of the Corporation of London, states that at the end of 1912 there were 329 open-type arc lamps in use. These were maintained by the City of London Electric Lighting Co. at £26 per lamp. There were also 94 Oliver and Excello flame arcs maintained at £17 10s., and 45 metal filament lamps (21 of these were of 75 c.p., 12 of 100 c.p., 9 of 200 c.p., 1 of 300 c.p., and 2 of 600 c.p.) in use during the year. Last year there were 332 open arcs, 92 flame lamps, and 46 metal filament lamps. The number of defective lamps reported was 63, for which deductions from the accounts amounting to £13 5s. 2d. were made.

As a result of 69 notifications by the Corporation 2 miles 1,893 yards of disused overhead wires were removed by the owners. During the year the number of private owners and companies owning overhead lines was 190 and 12 respectively

compared with 135 and 13 last year. Special attention has been given to the question of lines crossing roofs at a less distance than 6 ft., and as a result many removals have been ordered. There were given 429 notifications of defective materials, 125 of broken wires, and 168 of other contraventions of the bye-laws. The report also states:—

"Although the exchange telephone systems of the Post Office have been greatly extended, there is still a small demand for private 'direct' lines. The necessity of an immediate connection for business purposes is one cause of this increase, and there is nothing to prevent such lines being erected by wiring contractors for firms having premises in more than one part of the City, or between one or more different firms, subject, in the latter case, to license from H.M. Postmaster-General."

No less than 4,493 notices were given during the year by the Post Office to open manholes for repairs, exclusive of inspection, whilst 335 new services were laid, and several new boxes constructed. The City of London Electric Lighting Co. gave notices for laying 200 services, and for the construction of 9 new boxes. The Charing Cross, West End, & City Electricity Supply Co. gave 118 notices for laying services.

**The "Northampton" Magazine.**—The most recent issue of the Northampton Polytechnic Institute Day Students' Union Magazine contains a biography of Professor R. Mullineux Walmsley, abstracts of several engineering papers contributed by past and present students, as well as some miscellaneous information relating to the doings of the Students' Union. The latter is a particularly active body in the matter of entertainments.

**Defrauding a Supply Company.**—At Hebburn Police Court last week George Hunter, a labourer, was fined 40s. and costs or one month in default for short-circuiting a slot meter. The fraud had been going on for about two months, and the Northern Counties Electricity Supply Company has lost about 7s. 6d. When the meter inspector called he noticed pins being removed from the wires by another person who was also charged, but was unable to attend at the Court, on account of illness. The case against this defendant, Margaret Bruce, was adjourned for two weeks.

**NEW ASSISTANT** (reading out instructions in absence of engineer):—"If a feeder circuit-breaker blows out within five minutes of its being replaced, something serious is the matter and —"

**SWITCHBOARD ATTENDANT** (trying to blow arc out):—"We have been trying to blow this out for four minutes, so if it will hold out another minute we shall be all right."

## ELECTRICAL ENGINEERING IN THE MINING AND METAL INDUSTRIES

Correspondence on any of the subjects dealt with in this Section is cordially invited from our Readers.

The Editor is willing to insert letters over a *nom de plume*, but Correspondents should send their full names and addresses in all cases.

Letters should be addressed, "THE EDITOR, ELECTRICAL ENGINEERING, 203-206 Temple Chambers, London, E.C.," and should reach this office by the 21st of the month.

Correspondents are requested to write on one side of the paper only.

### ELECTRICAL DRIVING IN A METAL MILL

WE are enabled, by the courtesy of Messrs. George Johnson & Co., to give an account of the conversion to electric drive of their mills in the Birmingham district, where brass, copper and white metal is rolled cold in non-reversing rolls.

The mills were originally driven by two main steam engines. One, of 250 I.H.P., was used to drive the brass and copper mill, which contained nine pairs of rolls varying in size from 15 in. by 10 in. to 80 in. by 22 in., while the white-metal mill, which contains thirteen pairs of rolls varying in size from 12 in. by 18 in. to 20 in. by 72 in., was driven by a 150 I.H.P. engine. In both cases heavy flywheels were mounted on the main shafts of the roll train, and the drive was through spur gearing. Energy is now taken from the H.T. mains of the Birmingham Corporation Electric Supply Department at 5,000 volts 25 cycles, three phase. To guard, as far as possible, against failure of supply, H.T. feeders are brought into the works sub-station from two of the Corporation's sub-stations.

From the consumers' panel, which, together with the two feeder panels, is the property of the Corporation, three H.T. cables are carried on porcelain insulators to three oil-immersed switches controlling three transformers of the British Westinghouse Co.'s make; two of these are of 250 and 150 k.v.a.

FIG. 1.—BRASS AND COPPER MILL DRIVEN BY MOTOR BELOW THE FLOOR.

capacity for power purposes, the ratio being 5,000/440 volts, and the third of 6 k.v.a. capacity for lighting, with a ratio of 5,000/110 volts. All the transformers are three-phase. The secondaries of the power transformers are connected through switches to the bus bars of the L.T. switchboard. From this board cables are run to the large motors and distributing fuse boards. Mounted on the switchboard and in circuit with each of the outgoing cables is a Dorman & Smith "handle" type choking-tube fuse, also ammeters and integrating energy meters. Where the distributing cables are of large section, and the length of runs considerable, they are three-core, paper insulated and lead covered. In all other cases

the cables are V.I.R., either wire armoured or taped and braided, and carried in galvanised steel tubes.

The conversion was commenced by taking out the steam engine in the brass and copper mill, driving instead by means of a 250-B.H.P. Westinghouse motor, placed in a specially constructed chamber below the floor-level of the mill. This motor is of the three-phase slip-ring type, the synchronous speed being 250 r.p.m. The drive on to the roll train is by means of a spur wheel and pinion, the latter being mounted on a short shaft connected to the motor through a Bandy flexible coupling. Three grid-type resistance units which are connected in series with the rotor cables, are designed so

FIG. 2.—100-H.P. MOTOR DRIVING WHITE METAL MILL.

as to give a slip of 10 per cent. at full load of the motor, and thereby make use of the energy stored up in the flywheel. A three-pole oil-immersed stator switch fitted with overload releases and an ammeter, also a liquid-type rotor rheostat are fixed in convenient positions on the wall of the mill. The slip resistances were not fitted until the motor had been in operation for some time, and it is interesting to note that since their installation not only have the peaks in the load been less pronounced, but the drive has been much sweeter, and this without any appreciable increase in the consumption of energy.

Fig. 1 is a view of this mill, the motor chamber being below the floor, at the extreme right of the picture. The flywheel can be clearly seen.

After having thoroughly convinced themselves of the advantages of electric driving, Messrs. Johnson decided to take out the steam engine in the white-metal mill and replace it with a motor. Floor space being valuable, it was decided that the space occupied by the engine should be available for manufacturing purposes. The motor was therefore placed in a cellar adjoining the mill and driven up diagonally on to the flywheel of the main roll train. A 100-B.H.P., three-phase, slip-ring motor of the Phoenix Dynamo Manufacturing Co.'s make was installed. This machine runs at 750 r.p.m. and is fitted with roller bearings.

Mounted on the extended motor bed plate is a second motion shaft running at 243 r.p.m. and driven through a paper pinion and machine-cut cast-iron spur wheel. The drive on to the flywheel is by a heavy laminated Hendry belt. The rim of the flywheel was upwards of an inch out of truth radially, and was, moreover, only 12 in. wide. This was too narrow for a belt to transmit the required power. Both these difficulties were got over by building up a steel rim in two halves of boiler plate 22 in. wide by 1 in. thick. The plate was secured to the wheel by angle brackets bolted to the side of the rim by 1-in. through-bolts. The rim of the wheel was drilled and tapped, and fitted with set pins, by means of which the built-up rim was centred and given

additional security, the ends of the set pins being rivetted over flush with the face of the new rim. This arrangement has proved quite satisfactory.

Grid-type slip resistances which give 10 per cent. drop in speed at full load are connected in the rotor circuit of the motor.

Owing to the combined operation of the slip resistance and the "give" of the belt, a very smooth drive free from shocks to the motor is obtained. The change over from the steam to the electric drive was effected in a few hours without any time being lost in the mill. Fig. 2 is a photograph of the 100-B.H.P. motor in the cellar with the belt going up to the flywheel in the mill above. Fig. 3 shows one corner of the mill; the flywheel, with belt, can be clearly seen, and also the motor control gear on the wall, comprising reversing switch, ammeter, oil-immersed stator switch with automatic releases, and rotor rheostat. It may be mentioned that the reversing switch fitted to this motor and also to the 250-h.p. motor previously described have proved of great convenience when dealing with a "sticker" in the rolls.

On the removal of the steam engine mentioned above there was no further need for the boilers, so they were taken out and in their place was erected a two-storey building with cellar in which the following new machinery for dealing with tin foil was installed, consisting of one pair of breaking-down rolls, 12 in. diameter by 20 in., driven by a 50-h.p. slipping motor; one pair of intermediate rolls, 12 in. by 18 in., driven by a 15-h.p. squirrel-cage motor; three pairs of finishing rolls, 9 in. by 18 in. One of these is driven by a 25-h.p.

FIG. 3.—WHITE METAL MILL SHOWING RECONSTRUCTED FLYWHEEL DRIVEN FROM BELOW.

motor, and the other two by variable-speed, squirrel-cage machines, each having outputs of 13,  $8\frac{1}{2}$ ,  $6\frac{1}{2}$ , B.H.P., at 715, 480, 365 r.p.m. full-load speed. Nine cables are brought out from each variable-speed motor to a special pedal-operated tramway-type controller having a ratchet motion, so arranged that on depressing the pedal the motor starts up on the lowest speed, successive depressions of the controller raising the speed. A hand-operated lever enables the reverse series of operations to be effected. As these two pairs of rolls are used for very fine work it was found by experience to be necessary to have variable-speed motors, because what is a reasonable speed for rolling when once the metal is started in the rolls is altogether too fast for starting. This point will be appreciated when it is stated that Messrs. Johnson can roll down to 0.00075 in. in lead foil and 13,000 sq. in. to the lb. in pure tin; tin or lead foil of this thickness being exceedingly fragile. With the three speeds above mentioned any thickness of metal can be dealt with expeditiously and with ease. In addition to the motors already described, there are five machines varying from 5 to 15 B.H.P. installed in different parts of the works and used to drive embossing and tinning rolls, pumps, and fitting shops, &c.; these are all squirrel-cage machines having star-delta starters.

As in the event of an accident occurring it may be a matter of vital importance to bring the rolls to rest in the shortest possible time, an emergency switch has been provided at each pair of rolls connected to each of the two large motors. These switches are connected up in series with the no-volts release coils on the starters by means of two No. 18 S.W.G., V.I.R. cables run in G.T. conduit; the switches are placed on the roof trusses, and are operated through two cords with a red handle at the end of one and a black handle at the end of

the other. The red handle, which hangs lowest, and is the most obvious to a man in a hurry, has to be pulled to stop the motor.

The whole of the premises are electrically lighted by metal-filament lamps of 100, 50 and 25 watt capacity, those of the largest size being used for general lighting in the large mills. When a high-tension power supply is taken from the Birmingham Corporation mains they allow energy for lighting to be taken at the same rate as for power; as Messrs. Johnson obtain their energy at 0.8d. per unit, this obviously puts all rival methods of illumination out of court.

As regards economy, Messrs. Johnson state that the cost of electrical energy is considerably less than was the cost of coal alone, apart from the cost of coal and ash handling, stoker's wages, oil and water, &c.

On the score of convenience, the installation above described has fully justified itself. As current is obtained from the Corporation supply mains, energy is available at any moment day or night. The saving in space has been so considerable that a large addition to the revenue earning plant has been made, which could not otherwise have been done owing to the cramped position of the works. Also the annoyance caused by dirt and dust due to coal and ash handling, and the obstruction caused by carts and barrows has been got rid of.

In conclusion, we wish to express our thanks to Messrs. G. Johnson & Co. for permission to describe their interesting installation, and to Messrs. Moffett and Rosher, the Consulting Engineers, who designed and supervised the scheme, for furnishing us with the technical particulars.

## WATER POWER SCHEME FOR THE MOUNT LYELL MINES

WE have received from Mr. G. W. D. Moffat, of Sydney, some interesting notes on the large water-power scheme projected by the Mount Lyell Mining and Railway Co. of Tasmania, who have decided to instal generating plant and transmission lines at a cost of some £100,000 for utilising the power resources of Lake Margaret. This lake, in Southern Tasmania, is about eight miles from Queenstown, which is the mining town for Mount Lyell, at an altitude of 2,140 feet, and is 140 feet deep in places. The catchment area is 7.2 square miles. The rainfall recorded last year was 150 in., and was evenly distributed throughout the year. The lake has never been known to freeze. It is the intention of the Company to convey water from this lake from a depth of 20 feet for a distance of about three miles to a site where a high-tension three-phase power station will be erected, and current will be conveyed from this point for a distance of five miles, where a sub-station will be situated in the immediate vicinity of the now existing power house at Queenstown. The water will be conveyed for a distance of 108 chains by means of substantial wooden pipes, along fairly level country, until the pressure is increased by a steep gradient, and here steel pipes will lead to the power house at the foot of the incline down a gradient of 1 in 14. The static head available will be 1,152 feet. The discharge from the turbines will flow into a stream some 3 chains away. The work of clearing away the forest for the transmission conductors and pipeline is almost complete; an extra haulage plant is in the course of construction for the purpose of laying the pipes, and the site for the power station is almost cleared.

The power plant will consist of four 1,750 b.h.p. water turbines or Pelton wheels direct coupled to four 1,200 kw. alternators. Current will be transmitted at 6,600 volts to the sub-station, where by means of eight 700 kw. transformers the pressure will be converted to 500 volts 50 cycles. Motor generators will also be installed for obtaining D.C. for driving some of the machinery, which requires a flexibility of speed control. Two of the alternators are to be used as spares, although the transmission line is to be of ample capacity to carry the full output of the station.

It is interesting to note that in the last twenty years roughly  $1\frac{1}{2}$  million tons of timber obtained from the neighbouring forests has been consumed as fuel, and the Company's fuel bill per annum exceeds £50,000. Mr. Wright, the Company's Chief Engineer, has estimated that under present conditions they are paying between £24 and £25 per b.h.p. per annum, and that by the installation of the new power plant, power will cost the Company slightly under £8 per b.h.p. per annum. These figures include all such items as depreciation, interest on capital outlay, wages, maintenance, &c.

### A CENTRIFUGAL DISINTEGRATOR

A MOTOR-DRIVEN centrifugal disintegrator, especially intended for moulding sand for foundry purposes, has

CENTRIFUGAL DISINTEGRATOR.

recently been put on the market by the Maschinenfabrik Oerlikon (Oswaldstre House, 34-35 Norfolk Street, Strand,

W.C.). As may be seen from the accompanying illustration, the machine is compact and rigidly constructed. The frame is formed of four pillars bolted on to an iron base ring; and these pillars support the outer casing, which consists of a circular cover plate, carrying a feed hopper and supporting a wide conical flange, which extends downwards and acts as a shield to prevent dispersion of the sand treated in the machine. Below this hood, which is easily detachable, is mounted a vertical electro-motor, completely enclosed in a dust-proof casing and secured on the pillars by bolted cross arms. Keyed on to the upper end of the motor shaft is a horizontal disc, provided in the neighbourhood of its periphery with three concentric rows of staggered pins of circular cross-section. The sand shovelled into the feed hopper is flung outward radially by the centrifugal force against the rows of pins, between which it passes, to fall down against the flange of the hood in a finely-divided condition on to the floor, where it accumulates in an annular heap, and can then be removed for use. Any particles of iron in the sand will collect in the middle of the horizontal disc, and in front of the rows of pins, whence they can be easily removed after the cover is taken off. No further screening is required, even if the sand is to be used direct for moulding machine parts, &c. A 2-h.p. D.C. or three-phase motor running at about 960 r.p.m. is provided, and the machine can deal with between 6 and 10 cwt. of sand per minute, which is as much as two or three men can keep on shovelling into the hopper. A saving of 50 per cent. in wages is claimed over hand screening. The complete machine measures about 4 ft. in height by 8 ft. in diameter, and needs no special foundation.

**New Mining Regulations.**—It has been officially announced by the Secretary of State for the Home Department that the General Regulations under the Coal Mines Act, 1911, will come into force on September 15th. The regulations in so far as they affect the use of electricity in mines have been dealt with in *ELECTRICAL ENGINEERING*, February 6th, p. 74, May 1st, p. 244, and June 3rd, p. 395.

**Gas Ignition by the Filaments of Incandescent Lamps.**—The United States Bureau of Mines has recently published the results of a large number of tests carried out to determine whether standard and ordinary miniature incandescent lamps with both carbon and tungsten filaments cause ignition of gas at rest. It was found that the naked carbon filaments of standard lamps, burning at rated voltage, will invariably ignite explosive gaseous mixtures. If gas can reach the filaments of standard lamps without breaking the filaments or producing partial combustion within the bulbs, the explosive gaseous mixture is sure to be ignited. Several sizes of both standard and miniature lamps, when smashed while burning at rated voltage, will ignite gas. Standard lamps that do not usually ignite explosive gaseous mixtures may do so if the broken pieces of the filament cause a short circuit when the lamps are smashed. Low candle-power lamps of high voltage are less likely to ignite gas than those of higher candle-power or low voltage. The experiments did not prove conclusively that the spark occurring when filaments are broken is not the cause of gas ignition, but they gave support to that view. It was conclusively shown, however, that glowing filaments may ignite gas independently of any sparking.

**Prosecutions under the Special Rules.**—At Chesterfield on July 19th Mr. T. H. Elliott, Manager of the Langwith Colliery of the Sheepbridge Coal & Iron Co., was summoned for the following alleged breaches of the electrical special rules: (1) Neglecting to earth the metallic covering of a lamp-holder. (2) Not protecting live parts of a switch and fuse. (3) Not having a metallic switchbox earthed. The case arose out of the death of a lad who had apparently received a shock from touching an unearthed lamp-holder which had become live. The other two charges were the result of an examination made after the accident. Mr. Robert Nelson, Electrical Inspector of Mines, gave evidence as to the danger of such non-earthed parts. The defence was that the manager had taken every reasonable precaution by the appointment of qualified electricians to prevent contravention of the electrical rules. The Bench imposed a fine of £1 and £5 5s. as costs in regard to the "non-earthed lamp-holder," and dismissed the other two charges.

A somewhat similar case, but where, happily, the irregularity was discovered without loss of life occurring, was heard at Nottingham on July 23rd, when Mr. J. Whyte, Manager of the New London Colliery of the Digby Colliery Co., was charged first with omitting to earth the cover of the starter of a pump-motor, and secondly with having a cable in the pit which was non-insulated in parts. When it was explained that on the inspector's visit the starter was under repair, the first charge was withdrawn, but as regards the second charge, which related to a cable which was so worn that the conductor was bare in places, a fine of £5 with £3 3s. costs was imposed. It was stated that the proprietors of the pit had been spending on an average £75 per week lately in remedying existing defects.

## ELECTRIC MINING AND METALLURGICAL PATENTS OF JULY

### Mining.

The specifications of particular interest to mining electrical engineers, which have been published by the Patent Office during July, include in their number No. 3,903 of 1912 by E. A. Hailwood, which describes an igniting point for oil safety lamps having several radiating arms, so that one arm is always in position for igniting the wick whatever the position of the screw wick adjuster. This is an improvement on the design described in specification No. 18,415 of 1910. In specification No. 14,202 of 1912 by W. Thomson and J. H. Rothwell, a locking gear for an electric safety lamp is described, which allows the light to be switched on and off by a partial rotation of the upper and lower parts of the lamp, when the lamp is locked with either the lead plug or magnetic arrangement, or by a combination of the two. There are several improvements on the blasting machine described in specification No. 27,318A of 1906 are given in patent No. 22,450 of 1912 by the Sterling Telephone & Electric Co., Ltd., as communicated to them by Schaffler & Co., of Vienna. One end of the armature spindle and the driving gearing are supported in a single frame cast with the pole-pieces; and the second pole-piece is also fixed to this frame by non-magnetic bolts serving as distance pieces. A protruding sliding pin in the frame limits the motion of the driving gear and the clutch between driving-spindle and armature is of the ball type. The outer member is eccentric to the armature.

### Metallurgical.

The patents of particular interest to electro-metallurgists include No. 25,858 of 1912 by P. L. T. Héroult (New York). This is for a process for making high-grade pig-iron in which the pig as it comes from the blast furnace, cupola, or mixer is conveyed to a basic-lined electric furnace in a molten state, where the slag is maintained fluid, and is free from iron oxide. The atmosphere is non-oxidising, so that the sulphur is eliminated by the action of the slag. In specification No. 16,001 of 1912 by V. Stobie (Stobie Steel Co., Sheffield) the same object is attained by subjecting the iron in the electric furnace to the action of an iron-free slag, whilst carbonic acid gas from limestone which has been added to the bath is made to agitate the metal. In specification No. 20,557 of 1912, G. Michaud and E. Delasson (France) describe a method of refining tin in which an electrolyte, obtained by dissolving tin protochloride in water to which sulphuric acid, 1 per cent. of magnesium chloride, and 1 per cent. of boric acid are added. The tin is removed from the kathodes as it is formed. In specification No. 24,203 of 1912, A. L. C. Nodon (France) describes an electrolytic bath for recovering tin from waste tinned metals, &c., consisting of water 87.5 kg., sodium fluoride 6.0 kg., sodium pyrophosphate 0.5 kg., and hydrochloric acid 6.0 kg. Other ingredients may be substituted. In specifications Nos. 9,147 and 24,643 of 1912 by the Maschinenbau-Anstalt Humboldt (Germany), improvements in magnetic separators are described. The chief improvement in the first specification consists in providing auxiliary magnetising coils on the poles on rotary annular machines, so that the pole strengths may be adjusted independently of the main winding. An adjustable ring is also provided so that the main bearing is magnetically relieved of pressure on it. In the second specification the chief improvement consists of a design and arrangement of a single roller between the magnet poles so that the magnetisable particles are carried away by sharp ribs on it.

## A NEW PATTERN OF COMMUTATING POLE MOTOR

AFTER several years of careful experimenting, Newton's, Ltd. (Taunton), are placing on the market a commutating pole motor of special construction. The magnet system (with the exception of the commutating poles) is of cast-iron, and in one piece, and the frame is ventilated so as to provide better ventilation in a vertical direction than hitherto. The construction of the field system is shown in the illustration. The use of cast-iron combined with the particular position of the main field coils gives a better torque curve in motors having series or compound field coils. Owing, too, to the poles being solid and of special shape, the makers find it

possible to guarantee an absolutely silent running machine. One of the chief characteristics of the construction is that the usual magnetic leakage is absent. This, combined with the shortest possible path for main flux, makes a remarkably economical magnet system. The no-load losses are a minimum and the efficiency curve is very good. In a 10-B.H.P. continuous rated motor running at 850 r.p.m. the constant losses

CROSS SECTION OF COMMUTATING POLE MOTOR.

at full load equal 550 watts, and the variable losses 700 watts, giving an overall efficiency of 85.4 per cent. at full load, 85 per cent. at three-quarter load, and 83 per cent. at half load. The weight of these machines is about the same as of the usual steel construction.

A number of these machines have been supplied for quick-rated reversible lift motors, &c., as well as for continuous-rated machines.

The temperature rise is within the standard specified by the British Engineering Standards Committee.

SOUTH KENSINGTON, LONDON, S.W.

VISITOR—H.M. The KING.

### CITY AND GUILDS (ENGINEERING) COLLEGE

The City and Guilds (Engineering) College, the Engineering Section of the Imperial College, provides complete Courses of Instruction leading up to, and including, the highest specialised instruction for Day Students, with the object of fitting them to take leading positions in the industrial world as Civil, Mechanical or Electrical Engineers; Scientific Advisers, Investigators or Experts in the Engineering industries; and for those already practising their professions who desire to take up more advanced courses of training and research in connection with the branches of Engineering in which they are specially interested.

The Courses are as follows:—

**MECHANICAL ENGINEERING AND MOTIVE POWER**—  
Under the direction of Prof. DALBY, F.R.S., M.Inst.C.E.

**CIVIL ENGINEERING**—  
Prof. DIXON, M.Inst.C.E.

**ELECTRICAL ENGINEERING**—  
Under the direction of Prof. MATHER, F.R.S., M.I.E.E.

The following Diplomas are awarded to students who satisfactorily complete Courses of from two to four years:—

**The Association of the City and Guilds of London Institute** ... (A.C.G.I.)

For admission to the Courses qualifying for this Diploma candidates are required to pass the entrance or matriculation examination of the College held in September (application to be made not later than the first Monday); or to have passed the matriculation of the University of London in certain subjects.

**The Diploma of the Imperial College** ... (D.I.C.)  
(For advanced specialised or fourth year work.)

Further information and the Prospectus of the College may be obtained on application to the Registrar.

# QUESTIONS AND ANSWERS BY PRACTICAL MEN

## RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

## QUESTION No. 1,350.

It is required to operate three 20,000-volt isolating switches simultaneously by means of fixed handle and link gear. The handle will be about 9 or 10 ft. away from the switches. Explain how you would do this, giving approximate dimensions of the apparatus in a sketch. The device must be mechanically and electrically sound, as the switches are not for a laboratory, but for use under the worst conditions. The gear must not be expensive to construct.—"ABSONDERN."

(Replies must be received not later than first post, August 14th.)

## ANSWERS TO No. 1,348.

A double pole circuit-breaker is required for a 500 ampere, continuous-current, 100-volt supply circuit. The double-pole switches are to be operated by means of a solenoid (mounted vertically) through a toggle mechanism. The switches are to be jammed against the contacts in the "On" position. Give a suitable design for the toggle mechanism and switch contacts, &c., showing how the "holding on pressure," and the "initial pull" to operate the solenoid can be ascertained. No automatic safety devices are required in the circuit breaker.—"B. C."

The first award (10s.) is given to "M. M." for the following reply:—

The sketches (Figs. 1, 2 and 3) show a suggested design to meet the given conditions. Contact pieces of this type should be well made; not only should there be plenty of metal, but the laminations must make good contact. Some similar contacts under the charge of the writer are at a current-density of 300 amps. per sq. in., and yet, if kept in good order, work fairly well; if dirty they get very hot. Let the area of the laminations be  $1.5 \times 2.25 = 3.375$  sq. in., and attach to end of switch lever as per Fig. 3. The slight "set" allows a better contact to be made, and if a saw-draft is made as *a*, this will be a further improvement. The toggle levers A and B (Fig. 1) are each 2 in. in length; solenoid cores to rise and fall 1 in. This will give a horizontal movement of  $R = 0.55$  in. This amount multiplied by length of switch lever gives a break of nearly 3 in. It will be noticed that P, Q and T are fixed points; to save confusion, method of holding P is not shown, Q is adjustable by means of the nuts shown, and solenoid works round T to allow for alteration in centres. Any out-of-balance between the solenoid cores and the switch levers can be adjusted by means of the spring S; i.e., the spring will draw up the cores and open the switches when the solenoid is not energised. To save winding on the solenoid it will be best to work the iron, at beginning of stroke at a very low density, say 15,000 lines per sq. in., allowing for a leakage of 30 per cent. density in gaps =  $\frac{70 \times 15,000}{100} = 10,500$  per sq. in. A total pull of 6 lb. at beginning of the stroke should give an ample margin. Area of cores will then be obtained from:  $P = \frac{B^2 A}{72,200,000}$  where  $P$  = pull in lbs.,  $B$  = density in lines per sq. in.,  $A$  = area in sq. in.

$$\therefore A = \frac{3 \times 72,200,000}{10,500 \times 10,500} = \frac{1,444}{735} \text{ sq. in., and diameter} = 1.5 \text{ in. (approx.)}$$

The ampere-turns required may be calculated from: amp.-turns =  $0.3133 B l$ , where  $B$  = density in lines per sq. in.,  $l$  = length of gap in inches.  $\therefore$  amp.-turns =  $0.3133 \times 10,500 \times 1 = 3,290$  (approx.).

With No. 16 D.C.C. wire and a winding space 6.5 in. in length we can get eighty turns per layer. Eight layers =  $8 \times 80 = 640$  turns, and at 5 amperes we have  $640 \times 5 = 3,200$

FIG. 1.

FIG. 2.

FIG. 3.

amp.-turns. Loss in winding = 22.5 watts (approx.). This is about 0.4 watt per sq. in. of winding-surface; therefore temperature-rise should not be excessive. Pull at time of contact will very much exceed that at commencement of stroke; pull with different air gaps can be calculated from the above-given formulae. Below the cores, at K, a thin disc of leather or fibre will act as a buffer, and also prevent any tendency of cores to stick.

This is but an outlined method of procedure; to treat the question fully in detail would take up far too much space. If the 500 amperes is only reached occasionally, the switch might be made smaller. Again, it would be an advantage to fit a carbon break to minimise effect of sparking; also, by fitting a catch, the switch could be closed, and then current cut off the solenoid. This would effect a saving, and a small magnet could be arranged to release catch when desired.

The second award (5s.) is made to "S. C. J.," who writes as follows:—

The design of suitable switch contacts is given in Fig. 4. The fixed contact blocks call for no special comment. The brush contacts should be of laminated copper, backed by a steel spring. Renewable auxiliary contacts and a magnetic blow-out of the usual type should be fitted to each pole. The general arrangement of the switches, levers and solenoid is shown in Fig. 6, which also gives the connections. The small auxiliary switch cuts in a resistance, which decreases the "operating" current when the main switches are closed.

The design of a suitable operating solenoid is largely a matter of trial and experience. The initial pull required might be ascertained as follows, referring to Fig. 5:— $F = \frac{S}{2 \cos \theta}$ , and  $Fd = \frac{W}{2} D$ .  $\therefore S = \frac{WD \cos \theta}{d}$ , where  $S$  = pull of solenoid;  $\theta$  = angle of toggle levers to direction of pull of solenoid;  $F$  = push of toggle levers;  $\frac{W}{2}$  = weight of half-moving mechanism;  $d$  = vertical distance of  $F$  from fulcrum  $f$ ;  $D$  = vertical distance of  $\frac{W}{2}$  from fulcrum  $f$ . An allowance must be made for frictional losses. The holding-on pressure

# "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

## Specifications Published July 31st, 1913

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

**Names in italics indicate communicators of inventions from abroad.**  
**8,197/12. High-frequency Currents.** W. DUBILIER. To improve the efficiency of high-pressure or high-frequency induction coils or transformers, the circuits are arranged so that in the primary circuit of one transformer is an adjustable interrupter, across which is a condenser in series with the primary of a second transformer, whose secondary may be connected to the secondary of the first transformer. Two figures.

**13,463/12. Signalling and Controlling Ships' Courses.** D. J. MORGAN. Signals controlled by the hand-lever of a ship's steering telegraph indicate to other vessels a contemplated change in the course of the vessel. The helm is locked so that no course contrary to that indicated may be taken, and beams of light are projected on to the bridge so that the officer in charge can see that his orders are being carried out. Thirteen figures.

**15,927/12. Arc Lamp Electrodes.** M. A. HERWIG. A rigid metallic connector extends a short way into the electrode, with which it is intimately connected. The projecting end of the connector is secured in an electrode holder. Eleven figures.

**16,014/12. Nitrogen Fixation Furnace.** E. K. SCOTT. The electrodes of a polyphase furnace are arranged to give a concentrated conical flame when supplied with air from beneath. A steam generator is arranged to form a water-cooled roof to the furnace, so that the gases from the arc come in direct contact with it. Two figures.

**18,017/12. Humidifying Radiator.** H. H. GRUNDY. It is arranged that the heating element can be set to different positions within a casing which is provided with a moisture-producing water belt. The element may be spiral in form and adjustably mounted on tie-rods which hold the parts of the heater in position. Two figures.

**18,112/12. High-pressure Mercury Vapour Lamp.** B.T.H. Co. (*G.E.Co., U.S.A.*). The idle space in the envelope communicating with the arc chamber is filled with solid material so as to reduce the condensation of mercury, and thereby increase the pressure of mercury vapour in the lamp. Three figures.

**18,799/12. Static Spark Generator.** F. NEHMER. The apparatus is intended for lighting gas or inflammable vapour. The field plates on a stationary disc are of curved form extending from the circumference towards the centre, and of greater length than the radius. Curved sections on the rotor are also provided. Seven figures.

**24,484/12. Salient Pole Rotating Field Magnets.** F. LUNGSTROM. The windings are sub-divided and preferably formed of spirally wound strip. The sections lying between the centre and the end are supported against centrifugal force by projections on the core. Air spaces are arranged between the projections and the next section. One figure.

**27,535/12. Loaded Telephone Lines.** F. A. BECKER. This specification is an addition to No. 65/11. Inductive shunts are arranged between lead, and return at a maximum distance apart of  $\frac{1}{2}$  wave-length existing before their insertion. The total loss for each compensator is such that the maximum total effective ohmic resistance is  $(\sqrt{y^2+1}-y)$  times the reactance of the line capacity of the corresponding conductor elements from the frequency transmitted;  $y$  is the denominator of the fraction to which the line attenuation is to be decreased.

**29,149/12. Automobile Lamps.** A. A. GODIN. Two diametrically opposite stems for carrying the leading-in wires and a dead wire connecting the inner ends of the stems, which may be attached to the filament, are provided. This prevents the stretching of the filament. A suitable slotted reflector is also used to accommodate the stems, which are provided with non-rotatable terminals. Two figures.

**3,853/13. Leakage Telephony and Telegraphy.** SIGNAL GES. The receiving instrument is connected to the secondary of a transformer of which the primary and the leads connecting it to the submerged receivers are of very low resistance. A ship's hull may be connected to the low resistance primary of each of the two transformers necessary. Three figures.

## Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

**Distributing Systems, &c.:** ECKMANN [Load equalising on A.C. motor system] 9,174/13.

**Dynamos and Motors:** FRENCH WESTINGHOUSE CO., and LEBLANC [Automatic balancing] 16,949/12

**Electrometallurgy and Electrochemistry:** LEE and BRAME [Electroplating] 13,746/12; GES. FÜR ELEKTRO-OSMOSE and SCHWERN [Extraction of water] 10,875/13.

**Heating:** MIDDLECOAT [Water] 26,948/12; HASKELL [Liquid] 8,395/13.

**Ignition:** BLAKE [Spark plugs] 4,381/13.

**Incandescent Lamps:** HERRMANN, 8,198/13.

**Instruments and Meters:** COOPER [Recording] 17,388/12; SIEMENS-SCHUCKERT. [Meters, meter systems, and controlling relays] 25,831/12; FLAMAN [Remote revolution indicators] 26,685/12; CIE POUR LA FABRICATION DES COMPTEURS ET MATERIEL D'USINES A GAS and BROCC [Mercury motor meters] 8,601/13.

**Switchgear, Fuses and Fittings:** DYER [Controller contact fingers] 13,695/12; ELECTRICAL CONDUITS, LTD., and HEMMING [Conduit continuity] 16,104/12; RAILING and GARRARD [Interlocking starters] 21,120/12; [Motor regulating resistances] 21,504/12; ELLISON [Motor starters] 22,423/12; ABBATECOLA [Automatic controllers] 23,542/12; HORTON [Switches] 26,671/12.

**Telephony:** SIEMENS & HALSKE [Call grouping] 28,751/12.

**Traction:** DUCELLIER and GUILLOU [Track circuit signalling] 16,554/12; THOMAS and THOMAS TRANSMISSION, LTD. [Railway motor coaches] 16,852/12; KERR [Automatic train control and signalling] 5,092/13.

**Miscellaneous:** MORETTI [Electric discharge apparatus] 16,164/12; LAKE (*Fabrique Internationale d'Appareils a Magneto S.A.*) [Hand-driven lighting machine] 17,752/12; GROSST [Control for automatic photographic devices] 21,533/12; HORTON [Illuminated revolving advertising apparatus] 23,977/12; O'TOOLE [Discharging electricity from paper in printing machines, &c.] 29,735/12; MILHADO [Portable illuminated advertising pouch and silent salesman] 2,192/13; BRUNO [Clocks] 7,275/13; MORETTI [Discharge apparatus] 13,918/13.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Electrometallurgy and Electrochemistry:** A.G. FÜR ANILIN FABRIKATION [Electrolytic production of hydrosulphates] 13,901/13; BALLY [Transformer furnaces] 16,011/13.

**Instruments:** LANDIS & GYR [Base-plate] 15,811/13.

**Storage Batteries:** WACKWITZ [Grids] 15,719/13.

**Switchgear, &c.:** VOIGT & HAEFFNER [Switches] 8,409/13; KENNEDY [Train-lighting regulators] 15,580/13.

**Telephony and Telegraphy:** SIEMENS & HALSKE [Telephone circuits] 12,651/13; GIRARDEAU [Indirect excitation of oscillatory circuits] 15,869/13.

**Miscellaneous:** BURGER [Primary battery] 15,463/13; DE LA RIBOISIÈRE [Control of automobile doors, &c.] 15,648/13.

## Amendment to Specification

**9,142/11. Telephone Exchange System.** P. JENSEN (*Clement International Engineering Corporation, U.S.A.*). As a result of the extended investigation under Section 8 of the Act this specification has been amended by way of disclaimer.

## Restoration of Lapsed Patent

**22,819/08. Electric Clocks.** T. J. MURDAY. An order was made on July 25th restoring this patent, which lapsed last October, owing to non-payment of the renewal fee. (*ELECTRICAL ENGINEERING*, April 24th, p. 232.)

The following Amended Specifications may now be obtained.

**1,950/08. Telephone Switch Hooks.** J. E. KINGSBURY (*W. E. Co.*) (*Bell Telephone Mfg. Co., Antwerp*).

**9,142/11. Telephone Exchange Systems.** P. JENSEN (*Clement International Engng. Corporation, U.S.A.*).

**10,600/12. Footsteps for Telegraph Poles.** H. LENCH.

## Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

**Arc Lamps:** W. J. DAVY [Flame lamps with separate condensing chamber] 8,308/08.

**Dynamos and Motors:** V. A. FENN [Single-phase repulsion-induction motors with sectionalised stator winding] 238/06.

**Heating and Cooking:** VERITY'S, LTD. and H. S. SMITH [Liquid heating element] 8,471/08.

**Switchgear and Fittings:** F. J. B. COLLIS [Adjustable hemispherical reflector for portable or automobile lamps] 8,427/08.

**Traction:** B. T.-H. Co. (*G.E.Co., U.S.A.*) [D.C. track circuits for A.C. railways] 8,027/05; J. RILEY, H. H. C. SEYMOUR and E. K. PERKINS [Cab signalling] 8,788/07.

**Miscellaneous:** C. L. BURDICK [Spraying colour on paper, fabric, &c.] 8,703/03; H. USENER [Ship telegraph] 8,168/05; G. BARKER (*Boiler Room Economy Co., U.S.A.*) [Automatically controlled furnace dampers] 8,795/07; M. MÜLLER [Illuminated moving sign] 22,069/08.

# ADAMS IGRANIC

MOTOR CONTROL GEAR FOR NEWSPAPER PRESSES.

ADAMS  
M<sup>FG</sup> C<sup>Y</sup> L<sup>TD</sup>  
BEDFORD  
AND LONDON

will be given by  $P = \frac{F_1 d_1}{D_1}$ , where  $P$  = pressure on contacts;  $F_1$  = value of  $F$  when  $\theta$  is maximum;  $d_1$  = vertical distance of  $F_1$  from  $f$ ;  $D_1$  = vertical distance of  $P$  from  $f$ .

The mechanism should be so arranged that the angle  $\theta$  is nearly  $90^\circ$  when the switches are on, and it will then

FIG. 4.

FIG. 5.

FIG. 6.

be found that the current in the solenoid may be considerably reduced and still maintain an effective holding-on pressure. It may be mentioned that a switch of this description having no automatic features is usually termed a "contactor."

## ANSWER TO CORRESPONDENT

**ACCUMULATOR.**—If the battery has been out of use for some time, we should advise you to let the makers test its condition in order to ascertain whether it needs special treatment.

## AN AUTOMATIC COAL SAMPLER

**A**N ingenious piece of apparatus has been brought out by the Sturtevant Engineering Co., Ltd. (147 Queen Victoria Street, E.C.), in the shape of an automatic coal crusher and sampler. This should be of considerable use to coal buyers, as not only can a considerable amount of coal be crushed and a sample automatically taken in a very much shorter time than by the hand methods of crushing and quartering, but a thoroughly representative sample is assured.

The coal is fed into a hopper in 3 in. pieces or finer, where it is nipped between the fixed and rotating top crushing members and is subject to gradual reduction until discharged at the periphery below. A sample spout is placed opposite the discharge opening, and is arranged to remove a certain percentage of the product, 5, 10, or 15 per cent. The machine is very simple, massive, and compact, and amply strong to crush coal and the impurities found therein. It runs at slow speed, and is instantly adjustable for fine or coarse work while in operation by simply turning a hand wheel.

**The Magnet Magazine.**—In commenting on the excellent magazine of the General Electric Co. on page 443 of last week's *ELECTRICAL ENGINEERING*, we much regret that the Weichert Electrolytic Bleaching Apparatus was called, by an error, "Pleading apparatus."

**Electric Light Switching.**—A letter from Mr. W. Perren Maycock takes up the discussion which has been proceeding in a contemporary, and refutes certain allegations that the various systems of multiple control developed by A. P. Lundberg and Sons are complicated, and that the amount of economy obtained is not worth the complication entailed. Mr. Maycock points out that the main reason of their great success is convenience, and that the economy in current consumption which follows should be looked upon as a further incidental advantage.

## ELECTRIC TRACTION NOTES

It is reported that, owing to dripping of water in the Loetschberg tunnel on to the conductors, and other difficulties, the running of the full service, which was to have been commenced on August 1st, has been further postponed.

An extension of the Southend Corporation Tramways towards Thorpe Bay has been opened, and it is anticipated that by next spring the complete extension to Thorpe Bay will be completed at an estimated cost of £30,000. A feature of the scheme is that the tramways run in the centre of a road 100 ft. wide.

In the King's Bench Division last week the London County Council were successful in securing the appointment of a person to make a provisional valuation list with a view to the reduced assessment of the L.C.C. tramways in Islington in consequence of the reduction in profits owing to motor omnibus competition. It was stated that similar applications have been made to other Borough Councils, who have agreed. In the last two years the receipts of the L.C.C. tramways in Islington have dropped from £114,000 to £89,000.

In our note last week upon the decision of the House of Lords with regard to the rating of tramways in Tottenham, we inadvertently referred to the Light Railways Act instead of the Tramways Act of 1870. The decision of the House of Lords is to the effect that a tramway constructed under the Tramways Act of 1870 is not a railway for rating purposes, and is therefore not entitled to the three-fourths exemption of the General District Rate. Thus, that portion of the Metropolitan Electric Tramways, Ltd., undertaking which is constructed under the Light Railways Act enjoys the three-fourths exemption, whilst those sections constructed under the Tramways Act do not. In consequence of the above decision, the Accrington Corporation has ordered the repayment of several deducted sums representing three-fourths of the rate for two years, in districts where the Corporation tramways are laid. These sums had been deducted in consequence of the Appeal Court decision, which has now been reversed.

## TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

The latest edition of the handbook for wireless telegraph operators working installations licensed by the Postmaster-General, which has just been issued, is almost twice the size of the book which it supersedes, owing to the revision necessary on account of the regulations decided by the Radiotelegraphic Convention of London last year. The book may be purchased for 3d. through the usual Government channels. It treats mostly with ship and shore stations, and is divided into six sections. The first gives general information, the second deals with the form and acceptance of radio-telegrams, the third gives details relating to special radio-telegrams, such as corrections and inquiries concerning radio-telegrams, and abbreviations to be used for prepaid radio-telegrams, and for night service, &c. Part four deals with charges, accounts, and re-imbursements, while the fifth embraces the entire procedure to be observed in transmission of messages of different kinds. Part six contains the detailed service regulations appended to the international convention, and appendices deal with the international Morse code, official abbreviations, examinations for wireless operators, &c.

At a meeting of the Liverpool and District Amateur Wireless Association on July 31st, Prof. E. W. Marchant and Mr. L. S. Cohen were elected vice-presidents. The subject of protection against lightning risks was discussed, and it was suggested that a double-pole two-way switch could be used, for the purpose of earthing both aerial and also the

metal guy ropes, if thought necessary. On Saturday afternoon, August 9th, the Association will pay a visit to the Formby Power Station of the L. & Y. Railway, and some notes thereon were given at the meeting by the Hon. Secretary and Treasurer, Mr. Frith, of Crosby.

The new agreement between the Government and the Marconi Co. relating to the chain of Imperial wireless stations has now been issued as a Parliamentary White Paper, together with the Treasury minute on the agreement, and other papers. In answer to a question in the House of Commons, the Postmaster-General has stated that the recommendation of the technical sub-committee of the Imperial Wireless Committee, that before a contract should be entered into the terms should be submitted to an expert committee, is intended to mean that the specification and technical details should be examined by a committee of experts before a contract is made. Such a committee, consisting of technical officers of the Government departments concerned, with whom Mr. Duddell had co-operated, has done so.

On July 31st the Chorillos-Iquique cable failed, the Mollendo-Chorillos section having given out two days previously. Later advices stated that communication with Lima and all telegraph stations beyond in South America had been cut off, but Guayaquil, Santa Elena and Esmerelda can be reached without risk.—The Ottoman Government announced on the 1st inst. that telegraph offices had been opened at Adrianople, Kirkilisse, Baba Eski and Rodosto.—The "via Moulmein" route (via Rahang) has been down since the 27th ult., and traffic is being sent "via Kanburi."—The St. Jacques-Doson cable was down on the 5th inst., and telegrams to Tonkin are subject to delay.

## LOCAL NOTES

**Bavaria: Electricity Supply.**—According to the *Financial News*, the Bavarian Government has granted the Schuckert Co. and Messrs. Brown, Boveri & Co. a monopoly for the supply of electricity in the whole of the Upper and Lower Franconia. It is stated that the intention is to form a separate company to work the concession.

**Beckenham: Supply for Small Domestic Uses.**—The Council has adopted a suggestion by the Electrical Engineer to charge private householders at the rate of 1d. per unit for small domestic uses. Current will be taken from the lighting mains, and the additional units to be charged at 1d. will be based on the average of the previous lighting consumption. Thus, the cost of a double wiring system and two meters will be avoided.

**Chelmsford: Electric Supply Co.**—The question of purchasing the undertaking of the local electric supply company has been under discussion.

**Chorley: Electric Lighting.**—The question of an electricity undertaking has again been revived, and the matter has been referred to a sub-committee. The Council spent £800 in obtaining electric lighting provisional orders some years ago, but the matter was allowed to drop, as it became evident that the installation of plant by the Council would not pay. It is probable now that the Lancashire Electric Power Co. will apply for an order.

**Glasgow: Electricity Accounts.** The accounts for the year to May 31st show a net profit of £7,520, after meeting capital charges, and setting aside £50,307 for depreciation. It is recommended that the charge for private lighting purposes, churches and public schools, except domestic consumers, shall be 3½d. per unit for the first 600 hours' use of the maximum demand, and for heating to the same class of consumers the charge is to be reduced from 1½d. to ¾d. per unit. For domestic consumers, current for cooking, heating and other domestic purposes over 800 hours' use per annum of the maximum demand for lighting, where the current is taken for both purposes through the same meter, is to be reduced from 1d. to ¾d. per unit.

**New Plant.**—With a view to gaining information as to the latest developments in generating plant and central station arrangements, a deputation consisting of one member of the Electricity Committee and Mr. W. W. Lackie, the City Electrical Engineer, is to visit a number of large installations in America.

**Hove: Electricity Undertaking.**—The Corporation, in an endeavour to please all sections of the ratepayers now that

its Bill authorising the taking over of the Hove Co.'s electricity undertaking has passed through both Houses of Parliament, has announced its willingness to receive any suggestions from the ratepayers with regard to its management, which may be sent in. This somewhat unusual course of action is no doubt attributable to the very wide divergence of opinion among the ratepayers as to the policy of taking over the Company's undertaking, and the more or less narrow margin by which the final decision to do so was passed by the Corporation.

**Kingston-on-Thames: Electricity Accounts.**—The deficit upon the electricity undertaking for the past year, reported in our issue for July 31st, was discussed at the last meeting of the Corporation. It was pointed out by the Chairman of the Electricity Committee that, owing to the fact that the new Diesel engine plant which it was hoped would be running by the end of 1912 was not yet completed, the anticipated benefit from the reduction in the cost of fuel from the use of this plant did not come into the accounts for the period under review. It was also pointed out that all electricity undertakings throughout the kingdom have suffered from the increased cost of fuel, the absence of which would have made a very material difference at Kingston last year.

**Kingstown: Electric Lighting.**—Mr. Mooney, M.P., has, by his objection in the House of Commons, been instrumental in holding up the Bill which at one time included the electric lighting Order sanctioned by the Board of Trade to the Dublin Southern District Electric Supply Co., Ltd., for Kingstown. We gave the circumstances with regard to this Order on page 427 in our issue for July 17th. When the Order was before a House of Lords Committee, the Alliance and Dublin Consumers' Gas Co. opposed in order that they might apply next session for an Order for supplying electricity in the three neighbouring districts of Kingstown, Dalkey and Blackrock. Owing to opposition in the House the Board of Trade withdrew the Kingstown Order from the Bill, an action which has created considerable resentment. Mr. Mooney has applied for an evening to discuss the question, but at the time of going to press we have not heard whether this request has been complied with.

**London: City of London: Street Lighting.**—It is anticipated that the scheme for the reorganisation of the lighting of the City in equal proportions by electricity and gas will be completed before the winter.

**Lytham: Electric Lighting.**—The Council is inquiring as to a supply in bulk from the St. Amos-on-Sea Council.

**Workshop: Electric Heating and Cooking.**—In order to obtain practical experience as to the cost, &c., of electric cooking and heating apparatus, the Borough Electrical Engineer has agreed to instal apparatus of this type in his house, and to pay for current at an inclusive rate of £4 per annum, purchasing the apparatus himself. There was some opposition in the Council to the amount to be paid for current, but it was pointed out that if the Council agreed to purchase the apparatus, the Borough Electrical Engineer would pay the ordinary rates for current. Eventually, however, the proposal that Mr. Crowther should buy the apparatus and pay the amount for current mentioned above was passed.

**York: Extension of Supply Area.**—The Electricity Committee is considering the desirability of applying to the Board of Trade for a provisional order authorising the supply of electricity within a number of areas adjacent to the city boundaries.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

### Generating Stations, Sub-Stations, Mains, &c.

**Australia.**—Switchgear for power house at Canberra. Secretary, Department of Home Affairs, Russell Street, Melbourne. Sept. 1st.

This intimation from the *Board of Trade Journal* is only of use to firms having agents in Australia who can be instructed by cable. A copy of the specification may be seen at 73 Basinghall Street, London, E.C.

**Ballater.**—A scheme for taking a supply of electrical energy from the Aberdeen Corporation mains is under consideration.

**Burton-on-Trent.**—New sub-station switchgear. Borough Electrical Engineer.

**Egypt.**—An electric lighting installation is required for the town of Damanhour. M. le Directeur de la Section des Municipalités et Commissions Locales au Ministère de l'Intérieur, Cairo. October 31st.

**Limerick.**—A Local Government Board inquiry has been held concerning a loan of £9,500 for extensions at the electricity works.

**Lurgan (Ireland).**—A committee has been formed to consider an electric lighting scheme.

**New Zealand.**—An expenditure of £21,500 upon electric lighting is contemplated by the Tauranga Council.

### Wiring

*The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.*

**Bradford.**—New theatre. Architects, Chadwick & Watson, Leeds.

**Cambridge.**—Extensions to infectious diseases hospital.

**Darwen.**—New mill for Sunnyhurst Mill Co.

**Exeter.**—Electric lighting of hospital. Mr. H. Munro, Borough Electrical Engineer.

**Glasgow.**—Large hall for industrial exhibitions, &c. Town Clerk.

**Grantham.**—New library.

**Hastings.**—Electric lighting of several schools during summer holidays. Borough Electrical Engineer. August 11th.

**Liverpool.**—Labour Exchange. H.M. Office of Works, Storey's Gate.

**London: L.C.C.**—320 points at Middle Row school, Kensal Road, N.W. (See advertisement on another page.)

**Lewisham.**—New music hall.

**Luton.**—New school, Tennyson Road.

**Manchester.**—New nurses' home, West Didsbury. South Manchester Board of Guardians. Mr. F. H. Overmann, 49 King Street.

**Nottingham.**—Two new schools.

**Tottenham.**—New school at Vale Road.

**Tunbridge Wells.**—Cinematograph theatre.

**Wigan.**—New school at Pemberton.

### Miscellaneous

**Bristol.**—The Corporation has passed the following resolution:—"That the Electrical Committee be requested to consider with other committees interested the advisability of substituting electricity for gas where the latter is now used in buildings owned or controlled by the Corporation, to take such action as may be agreed upon, and to report to the Council thereon."

**Kirkcaldy.**—The Kirkcaldy and Dysart School Board requires electric lighting supplies. Architect, W. Williamson. Royal Bank Chambers. August 11th.

**West Ham.**—Twelve months' supply of electrical fittings for Union. Clerk, Union Road, Leytonstone, N.E. Sept. 4th.

## MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. George Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £70 5s. to £70 15s. (last week, £69 to £69 10s.).

**"Wotan" Battery Lamps.**—Siemens Bros. Dynamo Works, Limited, will shortly be revising and extending their "Wotan" Battery Lamp List, their past experience having enabled them to effect some material changes. In the meantime, they will be pleased to deal with any special inquiries that may be on hand. Communications should be addressed

to the Battery Lamp Department at Tyssen Street, Dalston, N.E. These lamps are manufactured for voltages from 1.5 to 18, from  $\frac{1}{2}$  to 50 c.p., and have filaments of drawn tungsten wire, as used in the standard type of "Wotan" lamp.

**Advertising.**—We have received from Messrs. Robinson, Greenly & Co. (116 Charing Cross Road, W.C.), who, as we have already announced, are acting as advisers and consultants in connection with electrical and general advertising, an attractive little booklet containing reduced examples of advertisements and other designs prepared by the partners in the firm, and a few words outlining their sphere of action.

**Bankruptcies.**—The first meeting of creditors in the bankruptcy of J. Swainson, trading as J. Swainson & Co., electrical contractor, 22 Booth Street, Manchester, will be held at the Official Receiver's offices, Byrom Street, Manchester, on August 14th, at 3 p.m. The public examination will take place in the Court House, Quay Street, Manchester, at 10 a.m., on September 19th.

## APPOINTMENTS AND PERSONAL NOTES

The salary of Mr. J. H. Cowell, General Manager of the Blackburn Corporation Tramways, is to be increased from £400 to £500 per annum by £25 increments.

The recommendation of the Leicester Electric Lighting Committee that the salary of the Chief Electrical Engineer, Mr. T. R. Smith, be increased from £600 to £900 per annum by annual increments of £100 as from January 1st, 1913, has, after considerable discussion, been passed with the alteration that the increase starts as from July 1st this year.

Plumber-jointers are required by the British Insulated & Helsby Cables, Ltd. (See advertisement on another page.)

Assistant engineers on the Line Side are required by the Constantinople Telephone Co. (See advertisement on another page.)

## COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

**London Electric Supply Companies.**—The Westminster Electric Supply Corporation has declared an interim dividend at the rate of 10 per cent. per annum less income tax on the ordinary shares for the June half year.—The Chelsea Electricity Supply Co. declared an interim dividend at the rate of 4 per cent. less tax on the ordinary shares for the June half year.—An interim dividend at the rate of 8 per cent. for the June half year has been declared upon the ordinary shares of the Kensington & Knightsbridge Electric Lighting Co.—An interim dividend of 6s. per share for the June half year less tax has been declared upon the ordinary shares of the City of London Electric Lighting Co.

An interim dividend for the June half year on the ordinary shares of the Brompton & Kensington Electricity Supply Co. has been declared at 9 per cent. per annum free of tax.

**Brush Electrical Engineering Co.**—As stated in our last issue, a loss of £7,710 was incurred last year. The directors' report points out that although the volume of business has been maintained, a proportion of the contracts on which the company has been working were entered into in previous years and at the lower prices which then prevailed. This circumstance, coupled with the serious effect of the coal and other strikes in the spring of 1912, and the consequent general advance in the cost of materials, has adversely affected the year's operations, and the directors regret that their expectations of improved results have not yet been realised. Another factor affecting the year's results has been the increased cost of insurance under the Workmen's Compensation Act, and the National Health and Unemployment Acts. As the result of conferences between the shareholders' committee and the directors, concerning the scheme of capital reorganisation, an issue has been made of £86,620 prior lien second debenture stock, which was offered to the first and second debenture-holders and ordinary shareholders. Of this amount £51,043 were allotted. The scheme for the reduction of the share capital is delayed pending the completion of the accounts for 1913. As already announced in our columns, the company has acquired a license to manufacture the Ljungström steam turbine, and the first set is now in successful operation at the Willesden power house of the North Metropolitan Electric Power Supply Co.

## SUMMARY

THE "glare" bogey is discussed in a short article. (Page 464.)

SOME notes on the arrangements for the next session and other matters relating to the Universities and Technical Colleges are given. (Page 464.)

Two books are reviewed on page 464.

AN article by Mr. E. P. Austin sets out the main principles to be followed in shop-window lighting, and discusses the different conditions met with in various classes of goods displayed. (Page 465.)

A NEW metal filament lamp which gives light of practically the same quality as daylight, and which can be used for matching colours, has been introduced. (Page 466.)

ELECTRICAL methods of measuring temperature were dealt with in a Paper by Mr. R. S. Whipple, read at the Cambridge meeting of the Institution of Mechanical Engineers. (Page 466.)

THE first half of the 300,000 h.p. development scheme of the Mississippi River Power Co., at Keokuk, is now complete. The generating station itself measures 900 ft. by 133 ft., and is to house 30 water turbine-driven vertical-shaft alternators, each capable of delivering 7,500 kw. at 11,000 volts, three-phase, 25 cycles. The pressure is stepped up to 110,000 volts by oil-immersed, water-cooled transformers for transmission to St. Louis and other towns and cities. Motor-generator exciter sets supplied from separate alternators are used. The engine room floor cannot be seen from the main switchboard except from an inspection gallery. (Page 467.)

SOME particulars showing the superiority of modern wire-drawn filaments over older types of lamp for train lighting are given. (Page 468.)

THE reasons for using loose coupling in wireless telegraph aerial circuits are discussed in our Questions and Answers columns. (Page 469.)

THE specifications published by the Patent Office last Thursday include two for geysers by G. R. B. Middlecoat and C. O. Haskell. C. B. Herrmann proposes to frost only the interior of incandescent lamp bulbs; and L. Abbatecola describes a cut-out for incandescent lamp circuits, utilising both the magnetic and thermal properties of the electric current so that the danger of the circuit being opened when the lamps are all switched on together is reduced. Two patents by R. Moretti cover details in the "shock" discharge system for wireless; and W. R. Cooper claims an arrangement for recording instruments in which a spark passes from the pointer through the recording strip. (Page 470.)

THE Bill authorising the Post Office tube railway has been passed by a House of Lords Committee, but the clause empowering the Post Office to supply current themselves has been deleted. An effort is being made to re-introduce this clause in the House of Lords.—A high-speed tube railway is projected from the Strand to the Crystal Palace. (Page 471.)

THE new Marconi contract has now been approved by the House of Commons.—It is possible that a Parliamentary Committee may be appointed to investigate the cost of working the telephones.—Some successful experiments are reported to have been made in Japan in wireless telephony. (Page 471.)

A PROFIT of £2,408 has been made on the year's working of the Halifax Electricity Department, and £5,204 at Greenock, and a surplus of £1,181 is reported at Maidstone. There is, however, a deficit of £214 at Aldrington, and £106 at Gloucester. New supply schemes are contemplated at Boston and Oulton Broad. (Page 473.)

A LOCAL GOVERNMENT BOARD inquiry has been held at Felixstowe (£4,729), and an inquiry is to be held shortly at Belfast (£35,000); wet air filters are required at Rochdale and Bridlington. (Page 473.)

THE goodwill of the Sunbeam Lamp Co. has been acquired by the Armorduct Manufacturing Co. (Page 474.)

### GLARE

WE are glad that, in the course of the discussion on "Photophthalmia" at the International Medical Congress this week, the eye specialists devoted the greater part of their attention to the seaside glare, and that the daily newspapers have mostly seized upon this particularly topical subject and have not raised a glare scare against electric light. There are exceptions, however. The *Daily Telegraph* suggests that "the time may not be far distant when everyone will have to wear coloured spectacles at night in the streets and other public places where the light is most striking." The latter proposal—apparently made in all seriousness—is one of those slight touches of exaggeration which are so dear to the modern journalist, but which, in such cases as this, certainly do not lend "an artistic air of verisimilitude to an otherwise bald but unconvincing narrative." There are, it is true, some cases in cities of unshaded gas mantles of high intrinsic brilliancy hung so low that they irritate and confuse the drivers of vehicles, but smoked glasses or amber-coloured spectacles are not the cure.

The talk of glare from metal filament electric lamps in houses is also frequently exaggerated and wide of the mark. Even illuminating engineers are too apt to forget that people in a room which is artificially lighted occupy themselves in looking at the objects illuminated and not at the source of light itself. So long as the lamps are well above the line of vision, and the general illumination of the room is good, the occurrence of photophthalmia need not be feared. It should be remembered that there is also a physiological effect from absolutely even artificial illumination, which may be summed up in the one word, dullness. There is too great a tendency on the part of illuminating engineers to aim at imitating diffused daylight, but necessarily at a degree of illumination which can only be a fraction of that of daylight itself. The depressing effect of carrying indirect lighting too far (well exemplified in the new lecture hall of the Institution of Electrical Engineers) should be avoided just as much as producing too sharp contrasts of light and shade by careless distribution of the lighting units with direct lighting. Let the illuminating engineer who takes daylight for his pattern remember that the light on a bright sunny day is preferable to that diffused from a dull, sunless sky.

### REVIEWS OF BOOKS

**Wiring Diagrams of Electrical Apparatus and Installations.** 258 pp. 9½ in. by 6½ in.; 439 figures. (New York: McGraw-Hill Book Co.; London: Hill Publishing Co.) 8s. 4d. net.

On the pages of this volume we have a series of over four hundred diagrams of connections embracing nearly every branch of electrical engineering except telegraphy and telephony, with practically no letterpress except the footlines to each diagram. In a few cases, particularly in the switchboard and substation sections, the drawings show general lay-out of apparatus, as well as actual connections, and, as might be expected, some of them refer to systems little used in this country. It is a little difficult to see just to what class of reader the diagrams are addressed, but, as the compiler remarks in his preface, "The reader will obtain information from them in proportion to his training and experience."

**Resuscitation from Electric Shock, Traumatic Shock, Drowning, Asphyxiation from Any Cause.** By C. A. Lauffer. 47 pp. 6½ in. by 4½ in. Six figures. (New York: John Wiley & Sons; London: Chapman & Hall, Ltd.) 2s. net; by post, 2s. 1½d.

In this little handbook the importance of artificial respiration as a method of resuscitation from insensibilities produced by electric shock, asphyxiation, drowning, &c., is insisted upon, and the advantages of the Schaeffer or prone pressure method are pointed out. Its action is clearly explained, and the method of application is described in detail. The author deals briefly with mechanical resuscitation apparatus, such as the Draeger pulmotor, but on the whole prefers the manual method, at any rate, for cases of electric shock.

### UNIVERSITY AND GUILDS TECHNICAL COLLEGE ANNOUNCEMENTS

THE City and Guilds (Engineering) College, South Kensington, S.W., now forms the engineering section of the Imperial College, and complete general, or highly specialised courses in electrical, civil, or mechanical engineering will begin early in October. The courses have just been rearranged as follows:—Mechanical engineering and motive power under the direction of Professor Dalby, who is Dean of the College; civil engineering under Professor Dixon; electrical engineering under Professor T. Mather. Besides the B.Sc. (Engineering) degree of the University of London, which may be obtained by qualified students, the diploma of the Association of the City and Guilds of London Institute (A.C.G.I.) may be awarded after two to four years' satisfactory work, and the diploma of the Imperial College (D.I.C.) may also be awarded for advanced specialised work. Much attention has of late been paid by the authorities to this kind of work, further particulars of which may be obtained on application to the Registrar.

Day and evening classes in all branches of engineering, including wireless telegraphy, metallurgy, etc., open on September 23rd and 22nd respectively at the Royal Technical College, Glasgow. A diploma course extending over three or four sessions may be taken. The engineering degrees of the Glasgow University are open to students at the Technical College, and particulars may be obtained from the Calendar, which is sent by post for 1s. 4d., and prospectuses, which are sent free on application to the Director.

The next session of the engineering department of the Edinburgh University opens on October 7th, but the entrance examination is held in September. Complete three-year courses in electrical, civil, or mechanical engineering qualifying for the degree of B.Sc. in engineering are provided. All particulars may be obtained from the Matriculation Office, The University, Edinburgh.

At the South-Western Polytechnic Institute a complete three-year course, leading to a diploma or University degree in electrical engineering, commences on September 29th. A scholarships' entrance examination will be held on September 22nd at 10 a.m. On the evening of this day a four-years' course preparatory for the electrical engineering and wiremen's examinations of the City and Guilds Institute will also open. Inquiries for fuller information should be addressed to the Secretary, South-Western Polytechnic Institute, Manresa Road, Chelsea, S.W.

Diploma or special courses in civil and mechanical, electrical or some other of the branches of engineering start at University College, London, on September 30th. The courses are arranged to cover the syllabus of the B.Sc. (Engineering) degree of the University of London, and facilities are also provided for advanced work and special measurements for those students who have taken a complete course and gained diploma or degree. Professor J. A. Fleming is head of the electrical engineering department. All communications respecting the College courses should be made as early as possible and addressed to the Provost, University College, London. The prospectus contains full information as to the courses of study, registration of students in the faculty of engineering (University of London), scholarships, &c. The College Calendar will be published in the middle of September, and may be obtained on application to the Secretary (W. W. Seton) for 2s. 6d., or by post, 3s.

We learn that Mr. C. H. Avery, of University College, London, and Mr. F. A. Eustace, of the City and Guilds Technical College, Finsbury, have been appointed to the heating and ventilating scholarships awarded by the Institution of Heating and Ventilating Engineers, tenable at University College.

**International Engineering Congress, 1915.**—Colonel G. W. Goethals, Chairman of the Isthmian Canal Commission and Chief Engineer of the Panama Canal, has been appointed Honorary President of the Congress, and will preside over the meetings to be held in San Francisco in September, 1915.

**Factory Regulations.**—The Home Secretary gives notice of alterations in the Factory and Workshop Regulations relating to the payment of moulders in iron and steel foundries, and defining the manner in which information is to be given to those employed as to the piecework rates relating to any particular work.

## SHOP WINDOW LIGHTING

By E. P. Austin

THE time has gone by when shop windows were considered lighted by suspending what are sometimes described as "bottles on a string" promiscuously amongst the goods displayed, serving to hurt the eyes of spectators rather than to illuminate the contents of the window. Sounder principles are now more often applied to illumination problems, with advantage to shopkeepers, and indirectly to the supply authority, which benefits by the advertisement of a well-illuminated window.

In general, the best example of illumination to follow is stage work, where the light is diffused about the stage, and the sources are hidden from the view of the audience. The main principles are that the source of light should be hidden or fixed well above the line of vision, and the light directed on to the goods. Light sources should not be fixed in too close proximity to the objects displayed or a patchy effect will be obtained, and light units of markedly different colours should not be used in conjunction. The application of these principles resolves the question itself into the correct choice of reflectors, in conjunction with the best positions of the lamps, and the correct types chosen by reference to their distribution curves. Brightly polished reflector surfaces are not always the best; sometimes a dull aluminium surface gives better distribution.

A simple problem is the window in the dimensioned sketch in Fig. 1. In this case six aluminium angle reflectors are used, spaced 20 inches apart, and using 60-watt tungsten lamps fixed vertically. The distribution curve of the reflector is shown in Fig. 3; it is obvious that the maximum intensity is on the goods, while sufficient reflected light is thrown on the pavement to attract attention. The total lumens in this case are approximately 3,000, yielding 2,000 effective lumens.

FIG. 1.

FIG. 2.

The vision is affected only by reflected light; there is no glare, and the goods are clearly defined at a distance of 100 ft.

A provision window dressed flat or nearly so requires different treatment, especially if the ceilings are fairly low. The prismatic glass reflector offers the best solution, and should be of the intensive type, the spacing and heights of such windows rarely lend themselves to the use of the extensive type of reflector. The colour of light units is an important point. To aim at daylight effects is somewhat misleading and not always desirable. A light that is rich in red rays has much to recommend it, particularly in the illumination of foodstuffs. Contrast, for instance, a butcher's shop using incandescent gas and one with the old-fashioned fish-tail gas burner, and notice the more attractive appearance of the meat in the latter case.

Windows which depend essentially on good lighting are those displaying fancy and white goods, hats, dress materials,

and tailors' and furniture shops. In determining the quantity of light required in individual cases, the reflective properties of different shades must be considered. A window that may alternate between white and dark goods must have a capacity for illumination suitable for the latter, with ample switching arrangements to prevent waste when showing light goods. The following table will serve as a guide in this matter, since it gives the reflective properties of different materials:

Approximate reflective values of different shades and surfaces:—

White blotting paper	...	82	per cent.
Foolscap paper	...	70	per cent.
Yellow paint, silk, &c.	...	40	per cent.
Blue paper	...	15	per cent.
Black cloth	...	1.2	per cent.
Black velvet	...	.4	per cent.

The nature and texture of fabrics affects their reflective values, which is largely a function of their transparency. Jewellery, pictures, and china ware all require their own treatment, influenced by the arrangement and proportions of the window. Such windows are usually shallow, dressed from top to bottom, very full, and close to the glass. Outside lighting with a "trough" type of reflector is very effective, and the light should be concentrated rather than diffused, since jewellery looks best when illuminated from a point. Millinery is best lighted from above with a well-distributed light. Tungsten lamps give the best colour effect in this case. Indirect, semi-indirect, or prismatic-bowl lighting are all eminently suitable for this class of work.

The arrangement shown in Fig. 2 is suitable for fancy goods and suspended tapestries, the analogy of stage lighting being closely followed in this instance. Tailors and furriers demand high candle power, since the dark materials have a high factor of absorption. Lamps should be kept well away from dark materials and suitably spaced intensive reflectors used entirely. Outside lighting by white flame arcs with reflectors to throw the light into the window gives good effects, but glare results from too much concentrated light, and the patterns of fabrics become indistinct and blurred under such conditions. The furniture window lends itself more to calculation than the previous examples. As a rule there is ample floor space, and the ideal space factor can be used, with prismatic reflectors. Again, absence of glare is most important. Furniture should show up in bold relief from its surroundings, yet light should not be unduly focussed to over-emphasise detail. Tungsten lamps give the most

FIG. 3.—POLAR CURVE OF LIGHT DISTRIBUTION FROM REFLECTOR USED IN FIG. 1.

desirable effects, and indirect lighting with white ceilings is pleasing in result. By the ideal space factor is meant the relation between the height above the working plane and distance between centres of lighting units that gives even illumination with a given reflector. For instance, the space factor for holophane intensive reflectors with 50-60-watt tungsten lamps is  $\frac{3}{4}$ , and 4 points in a window 10 ft. by 15 ft., suspended at a height of 7 ft., give a luminar intensity on the floor of seven foot-candles, approximately, allowing for a light ceiling. Semi-indirect lighting offers special advantages for furniture display. When a window is dressed in representation of a room, daylight effect is desirable and can be very closely approximated by having the top reflector of the semi-indirect lighting fitting of a delicate china-blue tint. Metal covers of this colour fitted over silvered reflectors also give a near approximation to daylight, and have been

used with considerable success. The scheme is also useful in drapery departments, where colour matching is important.

Outside shop lighting fulfils a two-fold purpose. Its primary object is advertisement, and illumination of the windows is its secondary object. Metal lamps are largely displacing arc lamps for this purpose. Outside and inside lighting should be carefully balanced, particularly when dark materials are displayed, or the window has a dark background.

Jewellery windows with fitted show cases divided into small compartments present considerable difficulties. The bulkiness of a lamp and reflector make it difficult to conceal them in a small case, so that one naturally turns again to outside lighting. Arc lamps with angle reflector fittings give good results, but the white flame should be used, as the yellow light is unsuitable for the display of precious stones. Pictures require essentially a "soft" diffused light. A refinement is to use special trough reflectors, which give excellent results when fitted to the top of large pictures. In conclusion, it is well to remember that shop window lighting is not to show off electrical fittings, but to give effective lighting.

### A DAYLIGHT LAMP

**SIEMENS BROTHERS DYNAMO WORKS, LTD.** (Incandescent Lamp and Fittings Department, Tyssen Street, Dalston), make the interesting announcement that they are placing on the market a Wotan lamp (with pure drawn tungsten filaments) which will give illumination of practically the same quality as daylight, at a current consumption of 1.5 watts per c.p. It will be known as the Wotan Verico lamp, and will provide drapers, storekeepers, colour printers, &c., with an illumination in which colours can be matched as safely as with daylight. Hitherto it has been necessary to use colour screens or filters to obtain such an effect, which, apart from the high initial cost, waste such a great amount of light, that the consumption per candle-power reaches 3 to 4 watts. The Wotan Verico lamp, therefore, is not very expensive in either initial or running costs, the colour filter effect being obtained by means of a special kind of glass. These lamps can be used with any type of reflector or shade which is not coloured. These new lamps are at present made in two sizes, of 70 and 140 c.p. respectively, for voltages from 100 to 130 and 200 to 250.

**"Job Line" Wire.**—An interesting case came on for hearing before Judge Woodfall at the Westminster County Court last week, in which Mr. Corfield, receiver for the debenture-holders of the Davis Electrical Co., Ltd., claimed £34 for cable supplied to Mr. G. Cohen, who was at the time of the transaction carrying on business as The Premier Electric & Hardware Co. (Golder's Green), who entered a counter-claim for about £70, as his reputation had suffered through the material proving faulty. A quantity of cable had been supplied by the Davis Co. to Mr. Cohen at £6 5s. per mile as "job line" cable, the ordinary price being about £11. It suffered from local faults, and had a lower insulation resistance per mile than 600 megohms, and used on a 240-volt circuit, the faults showed up. It was sold on the understanding that the Davis Co. would take back any that was defective, but after a time they refused to take back any more, as so much was returned. Mr. H. E. Davis, formerly managing director of the Davis Electrical Co., and now manager and buyer, said that the term "job line" implied that the goods were bought with all their faults and at the buyer's risk. The case, not being concluded, was adjourned till October.

**Water Sterilisation.**—Dr. Max von Recklinghausen describes in the *Electrical World* (New York) his industrial designs of apparatus for the sterilisation of water by ultra-violet light. For this method of sterilisation to be effective, the water must first be freed from any suspended matter. The largest lamps now in use require 375 volts across the electrodes when they pass a current of about 3 amperes. The quartz tubes are the same diameter (2 in.) as those in general use for lighting, but they are made U-shaped. The limbs are bent somewhat in the shape of a pistol, and fit into cavities in the sterilising chambers. They are started by tilting, for which they are put into a special box for the purpose. The lamp box and the quartz tube are fastened to a vertical metal plate, forming part of one of the walls of the sterilising chamber. Owing probably, it is thought, to the heating effect of the neighbouring branches of the U-tubes, the ultra-violet light produced is stated to be 50 times as great as that of a 110-volt, 3.5 ampere lamp. To deal with quantities of water up to 2,000 tons of water per 24 hours, not more than two of these lamps are required, but for larger quantities a construction consisting of a canal about 50 in. by 70 in. in cross-section, in the walls of which ten or a dozen of the 500-volt lamps are inserted, is used. Several of these equipments have been in use for some time. Portable sets would be of great use for military purposes.

### ELECTRICAL METHODS OF MEASURING TEMPERATURE

IN the course of a Paper entitled "Modern Methods of Measuring Temperature," by Mr. R. S. Whipple, read at the Cambridge meeting of the Institution of Mechanical Engineers, some interesting details were given of various electrical methods that are employed.

Electrical recording systems are sometimes applied to mercury thermometers. In one arrangement, designed by Mr. A. Barry, a high-resistance wire is stretched from the bottom of the bulb along the capillary. The apparent resistance of the wire is increased or diminished as the mercury falls or rises in the thermometer tube. By means of simple electrical arrangements the resistance of the wire can be measured from a distance, and the temperature deduced from the galvanometer readings; if a direct deflection galvanometer is employed the readings may be given directly in degrees of temperature. Mercury thermometers can also be arranged to sound an alarm when a given temperature has been obtained. A platinum wire is fused into the capillary tube of the thermometer at a point corresponding to the temperature at which it is desired to sound the alarm, a second wire being fused into the bulb of the thermometer. These wires are connected to a circuit containing a relay, which controls a switch capable of making and breaking a current sufficient to ring a large alarm bell.

Thermo-electric thermometers of the best class are made of platinum and an alloy of platinum and rhodium, but couples composed of silver or copper and constantan (a copper-nickel alloy) are often used for temperatures up to 700° C., and nickel with nickel-chromium for higher temperatures. The main difficulty in thermo-electric pyrometry is the control of the temperature of the "cold" junction. Melting ice is impracticable near a furnace; water-cooled heads to the pyrometer have been tried, but by means of leads of special alloys giving the same E.M.F. against copper as that given by the platinum-platinum alloy couple the cold junction may be placed at a distance from the furnace without expensive platinum leads, and may be kept at a constant temperature by a thermos flask arrangement or a steam jacket. The E.M.F. developed can be measured by direct deflection or potentiometer methods, and various ingenious recording instruments have been devised in connection therewith.

The resistance thermometer depends on the change in resistance of a platinum wire with temperature. The resistance can be measured by Wheatstone's bridge methods with direct reading slide wires and dummy leads to compensate for the resistance of the leads to the platinum element, or by direct reading instruments similar in principle to the ohmmeter. Recorders can be arranged in either case.

Thermo-electric and resistance thermometers both have a distinct upper limit of temperature beyond which they should not be employed. In the case of the resistance thermometer the limit is 1,200° C., above which temperature the mica frame disintegrates. The thermo-couple can rarely be employed above 1,400° C., because of the impossibility of finding a gas-tight protecting envelope that will last above this temperature.

In radiation pyrometers advantage is taken of the Stefan-Boltzmann law that the total energy radiated by a black body is proportional to the fourth power of the absolute temperature. In several optical radiation pyrometers, the light from the incandescent body is compared against that from a standard lamp within the instrument, or as in the Fery radiation pyrometer and others, the rays are focussed on to a thermo-couple connected to a galvanometer. The Paper concludes with some practical points regarding the application of various forms of thermometer and pyrometer to industrial operations.

**Iron and Steel Institute.**—Among the Papers to be read at the Brussels meeting of the Iron and Steel Institute from September 1st to September 4th will be one by Mr. O. Frick on "The Electric Refining of Steel in an Induction Furnace of a Special Type," and one by Dr. J. E. Stead and Prof. H. C. H. Carpenter on "The Crystallising Properties of Electro-deposited Iron."

**Electrical Fires in Chicago.**—During 1912 there were 71 fires in Chicago certified as being due to electrical causes. The damage is estimated at about £6,300. It appears that 11 were due to the short-circuiting of low-pressure cables, six to motor armature burn-outs, six to flat-irons left on circuit, five to flexible cords short-circuiting (the most serious fire was due to this cause), four to short-circuits on conduit, three to ignition of cinematograph films, three to inflammable material about incandescent lamps, and the remainder to miscellaneous causes.

## THE MISSISSIPPI HYDRO-ELECTRIC SCHEME

### I. General Description of Generating Plant

THE huge power-house at Keokuk, on the Mississippi, started at the beginning of last month to give a supply of electric energy over some 144 miles of transmission line at 110,000 volts 3-phase 25 cycles, from the fifteen, of the maximum number of thirty, water turbine-driven 11,000-volt alternators of 7,500-kw. capacity already installed. The turbines work under a normal head of 32 ft., obtained from the old Des Moines Rapids, which are now flooded by a dam 50 ft. in height, stretching nearly a mile between the Illinois and Iowa shores. The power-house, says the *Electrical World* (New York) is 900 ft. long and 133 ft. wide, while in addition the present project has included the creation of a lake 65 square miles in area, a lock 400 ft. by 110 ft., with a 40 ft. lift, which is as large as those at Panama; a dry dock 150 ft. by 463 ft., and a road and railway bridge 30 ft. wide, carried on the piers of the dam structure. Owing to the fact that the head of water available is so low, many interesting departures from general practice have been made.

The leading features of the hydraulic plant show the magnitude of the works involved. The dam is of the gravity section type, and is 4,278 ft. long, with two abutments measuring 210 ft. and 81 ft. respectively. It is made up of 119 arched spans, each having 6 ft. piers and 30 ft. openings, and is 52 ft. high, 29 ft. wide at the top, and 42 ft. at the bottom. The discharge is controlled by electrically-driven sliding steel gates, each measuring 11 ft. by 32 ft. The ice fender which guards the plant-forebay is 2,625 ft. long, of which 2,325 ft. is made up of concrete construction carried on 10 ft. piers, while the remaining 300 ft. is formed by a floating timber boom. The raising of the water-level has necessitated the raising of the neighbouring track of the Chicago, Burlington and Quincy Railway Co. by a new sea wall 1,110 ft. long and between 45 ft. and 73 ft. high. An entirely separate water-power plant is installed to furnish energy for operating the locks already mentioned. The upper lock gates are worked by compressed air.

The sub-structure of the power-house is 70 ft. high, measured to the engine-room floor, while the superstructure adds a further 107 ft. From the forebay on the Iowa side, the water passes through the racks and gate openings in the gate-house section of the building to four branch intakes, each 22 ft. by 7 ft. in section, for each 10,000 h.p. turbine. The draft tubes leave the bucket wheels as circular discharge openings 18 ft. in diameter, enlarging rapidly to 22 ft. 8 in. by 40 ft. 2 in. at the tail-race openings. The velocity of flow is 14 ft. per sec. at the top of the tube, but only 4 ft. at the point of discharge. Each turbine unit consists of a single 15 ft. runner with 20 buckets. The main turbine shafts are 25 in. in diameter and 21 ft. long. With the alternator field magnet in place, the total revolving weight is about 220 tons. This is carried by a thrust bearing and by two main-shaft bearings. On twelve machines the roller and oil-pressure bearing employed utilises oil at 225 lb. pressure, which normally keeps the 225-ton load lifted off the rollers. Oil is supplied by gravity to the upper bearings, being thence drained to the reservoir under the lower bearings, from which it is pumped to central supply tanks. Kingsbury thrust bearings, which require oil circulation at only atmospheric pressure, are to be used for the remaining three machines. The oil-pressure governors are mounted on the engine-room floor, with relay valves and regulating cylinders on the thrust-bearing gallery. Here also are the accumulator and receiver tanks and the triplex oil-pressure pumps. These are in duplicate, one set being driven from the main machine shaft through chain gearing, and the other by a separate induction motor. The motor-driven pumps are controlled by a pressure system, starting up only when the oil supply needs replenishing. In the governor pedestal on the engine-room floor are the speed-control element and anti-racing devices controlling the large balanced relay valves and the oil-pressure cylinders. The change of the control of the gate motion from its automatic cylinder operation to hand manipulation is provided for. There are four handwheels on the governor pedestal; two control the supply of oil to the valves, while the others serve to alter the speed of the unit by adjustment of the centrifugal device. One is purely mechanical; the other is electrical, its circuit being extended also to the main switchboard on the fourth floor, so that the operator there can adjust the governor setting and control the speed of any unit while paralleling, &c.

A longitudinal wall divides the power-house superstructure into two compartments, the engine-room and the gatehouse, the latter containing also the high-pressure transformer cells. Opening to the engine-room, but on a raised-gallery level, are the compartments containing the exciter sets, auxiliary transformers and switchboards, &c. On the upper levels are installed the low-pressure bus-bar structure and low-pressure oil switches and the 110,000-volt oil switches, lightning arresters, &c. On the fourth-floor level at the south end of the present plant, where it will occupy the centre of the

future completed building, the main switchboard is situated. The 15 main generating units are 7,500 kw. vertical alternators, having their rotating fields carried on the water-wheel shafts and running at 57.7 r.p.m. They measure 31 ft. 5 in. outside diameter. In height they extend 11 ft. 3 in. above the floor, the field collector rings being reached by platforms extending from the side-gallery level.

In addition a pair of 1,600 kw. auxiliary alternator sets supply energy at 440 volt, 25 cycles to the exciter motor-generator units. They are of the same direct-connected vertical type and are driven at 125 r.p.m., and each has its own direct-current exciter mounted on the shaft extension above the alternator. The exciter motor-generator sets can also be driven from the main 11,000-volt bus-bars through transformers. In case of emergency, connection can also be established with one of the duplicate 320 ampere-hour storage batteries used for working the control switches. Parallel operation of all the Tirrill regulators controlling the exciter fields is accomplished by means of series transformers in the machine leads, so that circulating currents are automatically compensated for. Opposite each main alternator is the corresponding 9,000-k.v.a. 10:1 star-connected step-up transformer with neutral point earthed. These transformers are oil-immersed and water-cooled, requiring 56 gallons of cooling water per minute to give an efficiency of 98.5 per cent. They measure 16 ft. by 8 ft. and are 25 ft. high over-all, weighing complete about 120 tons each. A 6-in. discharge pipe is fitted, so that in case of fire the oil can be immediately emptied into the tail-race. The cooling-water system is arranged in duplicate. Connection between alternator and transformer is made through the duplicate 11,000 bus-bars by motor-operated oil switches. Four alternators and four transformers constitute a section, and one section feeds each of the two St. Louis circuits. Another unit is to be ordinarily devoted to the local Keokuk service, and the remaining six will serve the Fort Madison and Burlington circuits at 11,000 volts.

The 11,000-volt copper bus-bars are each of rectangular section 3.5 in. by 0.375 in., and are mounted on porcelain pedestal insulators. The oil switches and disconnecting switches are on the floor above the bus-bars, i.e., the third floor. Concrete slab construction is employed throughout. One of the bus-bar sets extends solidly round the station, while the other is divided into sections, as already mentioned. These sections are connected by automatic oil-switches and reactances composed of 1-in. copper cable wound on wooden formers and are adjustable for a reactance of 4, 6, or 8 per cent. at 9,000 k.v.a. The short-circuit current of the alternators is only from three to five times their normal full load current, and the reactance of the transformers about 5.7 per cent., so that by the method of sectionalising adopted, the maximum current input into a dead short-circuit on the low-pressure bus-bars is limited to thirty or forty times the full load current of one alternator. In case of a dead short-circuit on one of the high-pressure bus-bars close to the power-house not more than two sections on each side of the one short-circuited will be affected. In no case does the pressure on sections adjacent to the short-circuited fall below 75 per cent. of the normal. The total current is practically constant from the instant of short-circuit onwards. The only automatic main switches in the station are the outgoing low-pressure line switches and the low-pressure bus-bar sectionalising switches. The latter are opened by inverse time limit relays, the settings of which are rather high in order to delay the opening of the circuit until no possibility of clearing up the trouble easily remains. Operation with non-automatic switches is extended as far as possible over the transmission system, as it is hoped thereby to eliminate a source of trouble and failure. An automatic feature, intended to secure rapid clearing of arcing earths or crosses, consists of a special contact in the Tirrill regulators which introduces resistance into the alternator excitation on the opening of the oil switch, so that the line pressure falls. As the switchboard is on the fourth floor and the engine-room floor is out of sight except from an inspection gallery, duplicate emergency cut-outs are provided at each machine station, one on the engine-room floor and the other at the side of the exciter gallery. By breaking the glass cover, the attendant can close the remote-control switch inside and so isolate the machine and disconnect its field supply in cases of emergency.

The high-pressure bus-bars, which are situated on the roof, are run in duplicate and consist of 2-in. painted galvanised iron pipe. They are supported on suspension insulators consisting of seven 10-in. discs. For branch connections 1.4-in. pipe is used. The vertical risers in the shafts connecting the bus-bars with the transformers are supported on seven-

part pedestal insulators mounted on the side walls. The high-pressure oil switches, which are of the solenoid-operated, non-automatic type, can be disconnected from the transformers by disconnecting switches with 4-ft. blades. The long high-pressure bus-bar has a switch for interconnecting the two 110,000-volt sections. For wholly disconnecting the transmission lines from all high-pressure apparatus in the building, switches having pivotted arms 12 ft. long and ending in vertical horn gap members, are mounted on the roof structure. These switches are worked through a crank lever, and when they are opened the lines are at the same time earthed. Choke coils and arrester gaps of the double-horn type with charging resistors connected between the upper and lower sets of horns are provided. In addition four aluminium cell arresters are used in each set. Three are connected in star to the phase wires, while the fourth forms an earth connection to the neutral point. In all cases the factor of safety has been taken as three. Minimum clearances of 3.5 ft. to earth and 5.5 ft. between phases have been used in the 110,000 bus-bar connections.

In conclusion, it may be said that very complete signalling and telephone facilities are provided, while the lighting of the engine-room is effected by 114 500-watt tungsten lamps, giving an illumination of 3.5 foot-candles on the floor level. The switch room is illuminated with diffused light through a skylight, behind which are tungsten lamps. Emergency lighting in case of shut-down is provided for by automatic switches, which connect about one-third of the lamps to the storage batteries, which can supply them for about an hour. The 1,500 three-pane window sashes which make up the movable sections of the 120 windows are motor operated, and so can be rapidly closed on the approach of a storm.

A description of the transmission system will appear in a future issue.

### METAL FILAMENT TRACTION LAMPS

IT is essential that the lamps used for lighting railway cars should be mechanically strong and able to withstand vibration and jolts. Even current consumption is less important than that of mechanical strength. Thus, for several years after the introduction of the "pressed" tungsten filament lamp railway companies preferred the old carbon filament lamp, which, although much less efficient, was a great deal more durable. The invention of the Mazda lamp, with a filament of drawn tungsten wire, however, has made

MAINTENANCE COSTS OF TRACTION LAMPS.

it possible for the advantages of high efficiency and strength to be combined. As a consequence, Mazda drawn wire lamps are now being used on many traction systems.

The accompanying diagram, which has been sent us by the British Thomson-Houston Co., Mazda House, Upper Thames Street, E.C., translates the improved strength of these lamps into reduced maintenance costs. The curve was prepared by the Chicago Rock Island Railway of America, and shows the average maintenance costs per car per month for lamps, renewals, and labour over a period of four years. In the first year the ordinary "pressed" filament tungsten lamps were used, and the average monthly cost per car was 18s. 6d. In the second year so-called "wire" lamps were used and the maintenance cost was 26s. 3d. Mazda drawn wire lamps were employed in the third and fourth years, and the average monthly maintenance cost per car was 14s. 5d. and 6s. 9d. respectively. The lower figure in 1912 was due to the improved strength of the Mazda lamps used in that year. The reduction in the average maintenance cost during the second two years is evidence of the great strength of Mazda drawn wire lamps.

### CATALOGUES, PAMPHLETS, &c., RECEIVED

**SUPPLIES.**—A new list to hand from the London Electric Warehouse Co., Department of the Brush Electrical Engineering Co., Ltd. (Manners Street, York Road, S.E.), illustrates a very large number of street lighting fittings, both with and without globes, for use with metal filament lamps. Ships' fittings, hand lamps, and accessories are also dealt with. A separate bulletin describes the "Economic" series fitting for metal filament lamps, and a further one deals with "Brush" arc lamps made under Bremer-Westinghouse patents. Other leaflets and folders embrace holophane ware for all purposes, "Benjamin" reflector fittings, and some handsome fittings for holophane reflector bowls and spheres, &c. The Metallum wire tungsten lamp in the usual sizes for private and public lighting, as well as for train lighting, is also listed, as is the "Candolite" electric candle fitting. In addition, mention may be made of the export price lists embracing Metallum lamps; 600, 1,500, and 2,500 megohms grade rubber insulated cables in sizes from 20 S. W. G. to 37/14 S. W. G.; and small shunt-wound D.C. motors of the protected type.

*Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."*

**AMMETERS AND VOLTMETERS.**—A new sheet from the General Electric Co., Ltd. (67 Queen Victoria Street, E.C.), brings to notice dead-beat moving iron "pedestal" or "controller" type instruments having ranges with maxima of 10 up to 600 volts, or 10 up to 600 amperes. These instruments may be used on either D.C. or A.C. circuits up to 600 volts; the movement is gravity controlled, though spring control may be substituted, and air damped. The accuracy obtained is that laid down by the British Engineering Standards Committee.

**MOTOR PANELS.**—Another sheet by the same company describes strong mistake-proof controller-type motor panels for pressures up to 650 volts. The panels are built up of standard apparatus consisting of ironclad circuit-breaker and controller, with or without shunt speed regulator.

**HOME CINEMATOGRAPH.**—A leaflet from the Wright Electrical Sales Co., Ltd. (94 Albion Street, Leeds), describes the "Wescoscope," which is a cinematograph apparatus for home use. The light is derived from an incandescent lamp fed from a battery.

**BALATA BELTING.**—The advantages of Silvertown Balata Belting, together with hints for belt users, are set forth in a new publication by the India Rubber, Gutta Percha, and Telegraph Works Co., Ltd. (Silvertown, E.). Prices and particulars of three- to ten-ply belting from one to 24 inches wide are given.

**ELECTRIC BLOWERS.**—A new type of hot-air douche, or electric blower, is described in a leaflet from Siemens Bros. Dynamo Works, Ltd. (Supplies Department, 38 and 39 Upper Thames Street, E.C.). The direction of the air current may be easily adjusted to any desired angle, which also enables the blower to be folded for convenience in packing. The consumption is given as 60 watts, and the weight as approximately 2 lbs.

Our Editor has been pleased to receive from Electrical Installations, Ltd. (27 to 28 Martin's Lane, Cannon Street, E.C.), a handsome and convenient blotter with which is ingeniously combined an alphabetical telephone index, scribbling pad, &c.

**Concentrated Filament Lamps for Photographic Purposes.**—Considerable experimenting has recently been done with Mazda electric lamps for photographing, copying pictures, making enlargements, printing films, and so on. Very satisfactory results have been obtained with six-volt concentrated filament Mazda lamps. They are being used successfully in automatic photographing machines, also for printing moving picture films. In both cases the lamps are equipped with parabolic reflectors to increase the intensity of the beam and concentrate the light over the relatively small area which it is desired to illuminate. It has been found that the operation of lamps at from ten to twenty per cent. over voltage produces a very white light, rich in the actinic rays which are necessary to affect the sensitised film of the photographic plate. For most photographic work the period during which it is necessary to burn the lamps is short; hence the loss of life, due to burning the lamps at over-voltage, is more than compensated for by the gain in photographic quality of the light obtained. The concentrated filament lamp is only one of many types of drawn-wire Mazda lamps manufactured at Rugby by the British Thomson-Houston Co., Ltd. For further information respecting these lamps application should be made to the company's London office, Mazda House, 77 Upper Thames Street, E.C.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,351.

A factory is to be driven electrically by motors aggregating about 200 h.p., varying in size from 3 to 50 h.p., and including a few of which the speed has to be varied. The only supply available is at 240 volts, 50 cycles, single phase. What class of motors and control would it be best to employ?—"P."

(Replies must be received not later than first post, Aug. 21st.)

### ANSWER TO No. 1,349.

State the theory of and advantages derived by using a loose-coupled inductance in wireless telegraphic receiving apparatus. Give the outline of construction of a suitable loose-coupled inductance for such work. Why is the iron core omitted in these, seeing that the two windings are quite independent, and apparently depend on transformer action.—F.

The first award (10s.) is made to "ANT" for the following reply:—

Any electrical circuit in which the capacity and inductance are high as compared with the resistance has a certain natural period of oscillation. The discharge of a condenser through such a circuit will take the form of an alternating current of a definite frequency, and if an alternating e.m.f. of this frequency is impressed on the circuit, it will cause a much larger current to flow than an equal e.m.f. of any other frequency. This property is made use of in wireless telegraphy by adjusting the inductance and capacity of the receiving circuit to correspond with the frequency of the received signals, thus establishing a condition of resonance and building up the received signals to a strength much greater than they would have if they were not in resonance with the circuit. The great advantage of a separate oscillating circuit for the receiver, connected through a "jigger" or loose-coupled air-core transformer to the antenna circuit, is the high degree of selective tuning which it renders possible, i.e., the ease with which the receiving circuit can be adjusted to respond readily to the frequency of the particular station from which messages are to be received, while being less sensitive to interruptions from other stations which may be transmitting at the same time, but at a different frequency. If the receiver is placed directly in the aerial circuit it will be equally affected by all the radiations picked up by the antenna, and although the antenna circuit can be tuned to some extent, this tuning cannot be so sharp as that of a separate oscillating circuit. If, however, the receiver is placed in another circuit which is inductively coupled to the antenna, oscillations in the antenna which are of the frequency to which the receiver has been tuned will be powerfully reproduced in the latter, while oscillations of any other frequency will affect the receiver but slightly. A further point in favour of the coupled receiving circuit, as compared with direct connection of the receiver in the earth wire of the antenna, is that at the earth end of the antenna the current is a maximum and the voltage a minimum, which are obviously conditions better suited to operate on a transformer than on a receiver which is usually of high resistance. Fig. 1 shows the arrangement referred to, the

oscillating circuit containing the receiver being tuned to the desired frequency by means of the variable inductance. It is also desirable to be able to vary the closeness of the coupling between the primary and secondary circuits of the jigger. If the coupling is too loose, only a portion of the energy available in the antenna circuit will be transferred to the receiver circuit, while if it is too tight, some of the energy given by the antenna to the receiver circuit will be returned to the antenna and lost, instead of being utilised in the receiver. The correct degree of coupling is best determined experimentally by adjusting the variable inductance and the degree of coupling until the maximum strength of signals is obtained. It will probably be found that less than 10 per cent. of coupling is required.

A simple form of jigger for a small receiving station is shown in Fig. 2, and can be made by hinging together two boards of convenient size (say about 1 ft. square), so that they can be opened and closed like a book. A flat coil consisting of a few turns of wire is mounted on each board, one coil forming the primary and the other the secondary winding. The degree of coupling is a maximum when the two coils are close together and lie parallel to each other, and is zero when the axes of the coils are at right-angles to one another. It is advantageous to wind the coils with cable composed of fine silk-covered copper wires twisted over an insulating core, in order to reduce eddy currents and skin effect. The ratio of primary to secondary turns will be

Fig. 1.

Fig. 2.

governed by the capacity of the aerial and the type of receiver used, and is most readily found by trial. The reason why an iron core is not used in such an oscillation transformer is that at the high frequencies employed in wireless telegraphy the losses in the iron due to hysteresis and eddy currents would be excessive. In fact, so much energy would be absorbed in this way that very little, if any, would be transmitted to the secondary circuit, the action of the primary currents being entirely masked by that of the eddy currents. A fuller account of the principles of application of loosely coupled transformers to both transmitting and receiving circuits, illustrated by mechanical analogies, will be found in the Yearbook of Wireless Telegraphy for 1913, pp. 338 *et seq.*

The second award (5s.) is made to J. F. ROMER, who writes as follows:—

In the ordinary wireless antenna the largest capacity is at the top, and when receiving signals the top becomes a region of maximum potential, while the part connected to earth carries maximum current. As most detectors work by a potential difference, the best place for them would be at the top of the antenna. This is very inconvenient, while if placed at any other part the detector would not be sensitive enough. The difficulty is got over by using a coupled inductance, which is in reality a resonance transformer, one coil being connected in series with the antenna and the other coil in series with a variable condenser. The detector is connected across the condenser terminals. The current in the antenna coil induces an oscillatory current in the receiving circuit and a maximum potential difference is produced between the condenser terminals. The detector is therefore in the most favourable position, and in effect the high potential of the top of the antenna has been transferred to a more convenient point. The antenna and the receiving circuit must be properly in tune with each other or the best effect will not be obtained. The two coils may be of equal size and consist of wire wound on wood or ebonite

## "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

### Specifications Published August 7th, 1913

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

16,104/12. **Conduit Continuity.** ELECTRICAL CONDUITS and J. R. A. HEMMING. A bifurcated or hollow rivet is driven through the socket so that the end of the rivet is dumped up and the tube slightly indented, as well as having the enamel removed. Four figures.

16,164/12 and 13,918/13. **"Shock" Discharge System for Wireless.** R. MORETTI. Water is supplied to the gap for cooling purposes through a hollow electrode. The exciters are arranged in series or series parallel, and are situated in an electromagnetic field. Each pair of electrodes may have a single cooling jet, or one central jet may be used. In the second specification it is proposed to immerse the electrodes in water. The electrodes may also be arranged concentrically, and provided with water-discharge chambers at their ends. The outer electrode may be rotated. Each specification has five figures.

16,534/13. **Railway Signalling.** L. DUCELLIER and H. GUILLOT. Near the end of a track section is a pedal comprising a magneto with an inclined steel plate close to the rail, so that it is depressed by the wheels of passing trains. When depressed, the magneto armature is moved so that eddy-currents are set up, which are used for the signalling. For single-line working two pedals are required. They are connected to a relay and condenser so that the relay breaks the circuit of the one pedal, when the other is operated. Three figures.

16,852/12. **Self-propelled Vehicles.** J. G. P. THOMAS and THE THOMAS TRANSMISSION, LTD. A construction of passenger rail coaches in which the prime mover is situated in the middle of the vehicle, is described. The chief features are that the floor and roof slope down from the centre, where is the driver's compartment, to the ends. The driver's compartment has inspection windows above the main roof. Four figures.

17,388/12. **Recording Instruments.** W. R. COOPER. The record is produced by a periodic discharge from the point of the needle through the paper to a metal electrode behind. The spark is adjusted by resistance in the primary of the induction coil necessary to feed the spark gap. The pointer is partially of glass or other insulator, and a second spark gap in series with the one used for recording is provided, so as to prevent disturbance of the needle. By means of a low resistance mercury switch, several circuits may be recorded by one instrument on the same paper. Seven figures.

17,752/12. **Magneto Hand Lamp.** W. E. LAKE (*Fabrique Internationale d'Appareils à Magneto, Switzerland*). The armature shaft carries the lamp, which rotates with the armature, within a fixed reflector. The armature is driven by a spring motor by means of repeated depressions of the lid of the casing of the apparatus. A press-button stop mechanism is also provided. Three figures.

23,542/12. **Automatic Controllers for Lighting Circuits.** L. ABBATECOLA. To prevent an electromagnetic cut-out opening on circuits where several metal filament lamps are lighted at once, the magnet is wound with a shunt and a series winding. The latter is differentially wound in two sections connected by a stretched wire. When this becomes heated by the main current it short circuits one section of the series winding, and the cut-out can operate. Two figures.

26,948/12. **Water Heaters.** G. R. B. MIDDLECOAT. The water passes through about six helically wound copper tubes  $\frac{1}{2}$  in. diameter, enclosed within an insulating casing and connected, the bottom of one to the top of the next. Inside each tube is an open resistor. Three switches control the heating. Two figures.

8,198/13. **Incandescent Lamps.** C. B. HERRMANN. Only the inner surface of the bulb is frosted, so that the efficiency is not so affected by accumulation of dust.

8,395/13. **Water Heater.** C. O. HASKELL. Cold water is passed into the lower end of the heater and conducted to the opposite end, then passed down in contact with outer bare resistors, and then passed up through an inner shell in contact with inner bare resistors. When once started, the cold water gets a preliminary heating from the steam from the preceding water. Three figures.

9,174/12. **Motor Load Equalising.** S. ECKMANN. This is a patent of addition to No. 11,597/12 (ELECTRICAL ENGINEERING, June 19th, p. 356). Automatic regulators to decrease the current taken by the flywheel motors alone when the total current increases, and *vice versa*, are provided. One figure.

### Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free. Summaries of some of the more important of these patents will appear in our next issue.

**Dynamos and Motors:** L. D. & M. Co., McLEOD and WILD [Brush-gear] 18,777/12; B. T.-H. Co. (*G.E. Co., U.S.A.*) 21,761/12; B. T.-H. Co. and TAYLOR [Ventilation] 21,866/12.

**Electrometallurgy and Electrochemistry:** DE MARE [Ozone generators] 20,988/12; B. T.-H. Co. (*G.E. Co., U.S.A.*) [Furnaces] 26,082/12.

**Heating and Cooking:** BRITISH ELEC. TRANSFORMER CO., BERRY and LONDON [Viewing interior of oven] 16,960/12; STUBBING [Heated garments] 28,846/12.

**Ignition:** BOSCH [Automatic time adjuster] 4,692/13.

**Incandescent Lamps:** LUDDECKE and BRIMSDOWN LAMP WORKS [Furnaces for treating metallic filaments] 6,952/13.

**Switchgear, Fuses, and Fittings:** B.T.-H. Co. (*G.E. Co., U.S.A.*) [Relays] 12,060/12; ACKERMAN [Reverse current circuit-breakers] 27,090/12; CHUBB [Aluminium cable connectors] 2,146/13; BERGMANN A.-G. [Electro-magnetic heavy-current switches with automatic release] 2,778/13; SIEMENS & HALSKE [Automatic short-circuiting of lightning arresters] 14,214/13.

**Telephony and Telegraphy:** AITKEN [Telephone exchanges] 16,906/12; DUBILIER [Wireless oscillations] 19,763/12; RICHARDSON [Protective attachments for telephone mouth and ear pieces] 20,580/12; LAGUS [Telephone apparatus] 21,351/12; HAMMER [Telephones] 24,408/12; SHAW [Telegraph transmitters] 8,024/13; STILLE [Telephonic reproducers] 9,644/13; KELVIN & JAMES WHITE and FIELD [Loud-speaking telephones] 9,732/13.

**Traction:** POLLAK (*Elektro-Motoren-Werke Hermann Gradenwitz*) 20,446/12; STRAITON [Switches for trolley wires] 24,384/12; DAVIDSON [Tramway-point operating] 26,145/12; TH. GOLDSCHMIDT A.-G. [Rail bonding] 1,179/13; THOMAS and THOMAS TRANSMISSION [Power transmission and control] 12,841/13.

**Miscellaneous:** CARLSTEDT [Timing races] 17,666/12; SCHULER [A.C. electro-magnetic striking tools] 18,184/12; JAMES [Protecting submerged structures from barnacles, &c.] 19,297/12; CLUDERAY [Time alarms] 24,261/12; LOUDON [Lift signalling, &c.] 4,256/13; STILLE [Aluminium-acetone light sensitive cells] 9,060/13; MAGNET-WERK GES. EISENBACH [Lifting magnets] 13,911/13.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Dynamos and Motors:** A.E.G. [Cooling] 16,391/13.

**Heating:** LACASSE [Radiator] 16,485/13.

**Incandescent Lamps:** WOLFRAM-LAMPEN A.-G. [Manufacture] 15,824/13; KANAZAWA [Manufacture of cobalt filament] 16,481/13.

**Switchgear and Fuses:** POLLAK [Automatic circuit-breakers] 15,950/13.

**Telephony:** SCHIESSLER [Relays] 15,179/13; SIEMENS & HALSKE [Prepayment meters] 16,376/13.

**Miscellaneous:** ARNOLD [Reproduction of electric variations] 29,384/13; KRUPP [Magnetic separators] 14,426/13 and 14,427/13; ELIA [Submarine mines] 16,379/13.

### Amendment of Specification

14,015/12. **Wireless Telegraphy.** W. DUBILIER. An error in this specification (ELECTRICAL ENGINEERING, May 29th, p. 310) has been corrected.

### Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

**Dynamos and Motors:** B.T.-H. Co. (*G.E. Co., U.S.A.*) [Unipolar A.C. machines] 8,569/05; J. E. NOEGGERATH [Armatures and collector rings of homopolar machines] 8,415/08.

**Electrochemistry and Electrometallurgy:** A. S. R. WAINWRIGHT and F. J. MANN (executors of G. J. ATKINS) [Electrolysis: vat construction] 9,706/06.

**Ignition:** C. A. DAY (*Fabrik Elektrischer Zünder, Germany*) [Miner's safety lamps] 9,103/04; P. JENSEN (*L. G. Bartlett, U.S.A.*) [Gas and acetylene lamps] 8,730/08.

**Incandescent Lamps:** H. J. HADDAN (*Electroden-Ges., Germany*) [Finely divided zirconium, thorium, &c.] 9,384/04.

**Telephony:** J. E. KINGSBURY (*W.E. Co., U.S.A.*) [Prepayment slot meters] 9,714/06.

**Traction:** SIEMENS BROS. (*Siemens & Halske*) [Local and central control of points and signals] 8,968/08.

**Miscellaneous:** G. BARBOU [Filling bottles to a predetermined height] 9,325/07; EXPANSION SPRINKLER SYNDICATE, J. FIDDES, and J. F. WATT [Automatic fire-alarms] 9,535/07; W. and A. C. McWHIRTER [Signalling and recording changes in level of liquid] 8,920/08; R. T. GATES [Portable disappearing targets] 9,052/08.

bobbins. The coupling is adjustable by varying the distance between the two coils, either directly or by sliding one coil inside the other. Loose coupling is used, in order to cut out atmospheric effects. An iron core is not used, because the signals received are produced by oscillatory currents of so high a frequency that all the energy entering the antenna would be dissipated by hysteresis and eddy currents in the iron, however finely it was laminated.

## ANSWERS TO CORRESPONDENTS

**EXAM.—CANDIDATE.**—The following books will be useful to you in reading for the examination of the Association of Mining Electrical Engineers:—"Application of Electric Power to Mines and Heavy Industries," by W. H. Patchell, "Electric Practice in Collieries," by D. Burns; and "Electrical Mining Installations," by P. W. Freudemacher. We can supply you with any of these. You will, of course, have to make yourself thoroughly acquainted with the Home Office Electrical Mining Regulations.

## ELECTRIC TRACTION NOTES

The Bill authorising the construction of a double track tube railway by the Post Office for the conveyance of mails across London was passed last Thursday by a committee of the House of Lords, under the chairmanship of Lord Newton. The tube, it was stated, is to be 9 ft. in diameter, with two tracks of 2 ft. gauge, and the trucks are to be of steel and 11 ft. 7 in. long. Owing to the opposition of the London Electric Supply Companies to the clause giving the Post Office power to supply energy from the Post Office generating station at Blackfriars to the railway and to the post offices on the line of route, though amended by the House of Commons committee, was struck out. A clause was also inserted putting the Post Office under a penalty of £10 an hour for any interruption, due to negligence, of electricity, gas, or water supply. This is the clause inserted in all the tube railway Bills. Evidence was given for the Post Office by Mr. W. Slingo (Chief Engineer) and Mr. H. C. Gunton (Principal Power Engineer), and for the Supply Companies by Mr. G. W. Partridge (Chief Engineer, London Electric Supply Corporation), Mr. Frank Bailey (Chief Engineer and Manager, City of London Electric Lighting Co.), and Mr. E. W. Seale (Secretary and Manager, Charing Cross, City and West End Electric Lighting Co.). The estimated consumption by the railway is about 480,000 units per annum. With this load the cost of generation by the Post Office would be reduced from 0.878d. per unit to 0.627d., and the cost per unit delivered would be reduced from 1.486d. to 1.077d. The additional capital expenditure for electrical equipment by the Post Office is £76,120, comprising £14,100 for the track, £1,450 for ventilation, £400 for telephones, and £44,330 for equipment between points of supply in substations and the track. The Supply Companies had not been asked to tender, but now that they knew the requirements, they said that they could supply at £4 per kw. of maximum demand per annum plus 0.5d. per unit. If the supply to the post offices on the route of the railway was taken away from them, they would be compelled to charge higher prices for the supply to the smaller post offices in London left to them. The average price now actually paid is 2.1d. per unit. In allowing the Bill to proceed, the Chairman said that the Committee considered that that part of the Bill which related to the supply of electricity had not been proved. It was unable, however, to express an opinion whether the supply by the Post Office would be in the interest of public economy.

On Monday the House of Lords went into Committee on this Bill, when it was announced by the Lord Chancellor that an amendment would be introduced by the Government on Report to restore to the Bill the clause giving power to the Post Office to supply electrical energy for the railway and

post offices on the route from its station at Blackfriars. The Report stage was reached on Tuesday, and was continued yesterday. Lord Newton submitted that if the Bill was passed as amended by the Select Committee, the tube could be made and the Post Office could come to Parliament next session with a considered proposal relating to the supply of electricity. A public department, he said, when appearing before a Private Bill Committee, must be treated as any other Bill promoter. The Marquess of Crewe stated that the Post Office had always intended inviting tenders for the electricity supply from the supply companies and local authorities, when, if a real appreciable saving would result from taking an outside supply, that course would be adopted. On these grounds, he asked the House to agree to the reinsertion of the clause. The Earl of Donoughmore, speaking as Chairman of Committees, from the point of view of private business, regretted the course the Government were taking. It amounted to a claim of privileged position and a right to review the decision of a Select Committee when not to the liking of the House. The Marquess of Lansdowne and others also pointed out that the unusual course suggested by the Government would, if adopted, constitute a not very convenient precedent.

It is stated that a Bill will be introduced into Parliament next session for the construction of a tube railway on the Kearney high-speed system from the Strand to the Crystal Palace. The distance is 6½ miles, and there would be intermediate stations at Westminster Bridge Road, The Oval, Brixton, and Herne Hill. The journey would be accomplished in ten minutes.

The Glasgow Corporation is considering the appointment of a special committee to report on a scheme of electric tube railways between the east and west of the city.

It has been announced that the part of the Canadian Pacific Railway system crossing the Rocky Mountains between Rossland and Castlegar is to be electrified. Direct current at 2,400 volts will be used, with overhead trolley.

The Tyneside Tramways & Tramroads Co. report a total surplus for the half year of £5,445. The final available balance of £4,864, after payment of debenture interest, &c., including the amount brought forward, is to be applied to the payment of a 5 per cent. dividend, and a dividend on the ordinary shares at the rate of 3 per cent., with £1,200 placed to reserve, and £724 carried forward.

## TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

The new contract between the Post Office and the Marconi Company for the Imperial Wireless Chain was passed by the House of Commons last Friday after a lengthy discussion.

From correspondence which has passed between the Post Office and Mr. C. S. Goldman, on behalf of the Parliamentary Telephone Committee, it appears that the investigation of the cost of working the telephones has proved more difficult than the Post Office anticipated. As soon as this inquiry is complete, which will not be before next session, opinions are to be invited "from all quarters before any action is taken to put the new rates in force." It appears that a Parliamentary Committee is to be appointed for this purpose. Apparently also the Post Office objects to the formation of a central advisory committee of business men, on the lines of those successfully appointed by the Board of Trade, which could deal with both rates and the general policy of administration. Without such a committee, Mr. Goldman points out, the local advisory committees appointed by the Post Office are not of such great value as they would otherwise be.

The *Electrical Review and Western Electrician* (Chicago) contains a note to the effect that the wireless telephone apparatus which Japanese officials of the Department of Communications are credited with having invented was success-

*When corresponding with Advertisers, please mention "Electrical Engineering."*

fully operated early in June, according to statements made by the parties concerned. From the Yokohama station limited conversations have been carried on with Japanese steamships as far distant as sixty miles.

The Gesellschaft für drahtlose Telegraphie have issued a special number of the *Telefunken Zeitung* to commemorate the 10th anniversary of the foundation of their business. The frontispiece illustrates the new liner *Imperator*, and a special article is included on projected long-distance wireless schemes, together with a review of the progress of the Telefunken systems during the last ten years and several other notes and illustrated articles relating to wireless telegraph schemes in various parts of the world.

Two new telegraph cables between this country and the United States are, we learn, to be laid *via* the Azores.

For the first time on record, says the *Electrical Review and Western Electrician* (Chicago) telegrams containing twenty-eight words were transmitted from the wireless station at Sayville to Nauen by means of Count Arco's high-frequency apparatus, on July 12th, with an expenditure of only six kilowatts, while recently, for the transmission of mere sounds over 100 kw. were needed.

At the meeting of the Spanish & General Wireless Trust, Ltd., which is one of the Marconi group of companies, a profit for the year of £4,654 was announced, which has been carried forward. Stations have been constructed at Arnaguez (near Madrid), Barcelona, Soller (in the Balearic Islands), Cadiz, Vigo, Las Palmas, and Teneriffe (in the Canary Islands).

The *Electrical Review and Western Electrician* (Chicago) announces that direct wireless communication between America and Asia has been established by night between the U.S. Army Signal Corps station at Nome, Alaska, and the Russian station at Anadyr, Siberia. There is a chain of four Russian stations between Anadyr and Vladivostok. Before a commercial service is established an agreement will have to be come to between the two countries.

We are advised, as from the 7th inst., that all telegrams for Venezuela are subject to censorship. All routes *via* Colon and Galveston to places in Peru and beyond are again restored, and the Chorillos-Iquique cable was repaired on 8th inst.

## LOCAL NOTES

**Aberdeen:** *Electricity Supply.*—A scheme is under consideration for a supply of current by the Corporation to Banchory, Aboyne, and Ballater.

**Aldington:** *Electricity Accounts.*—After payment of capital charges, a loss of £214 has been made on the undertaking, as compared with £246 for the previous year. The total sales amounted to 56,738 units as compared with £53,371. The deficit has been met out of general rates.

**Boston (Lincoln):** *Electricity Supply.*—Messrs. Crompton & Co. have given notice that they will apply for a provisional order for this district.

**Exeter:** *Electricity Accounts.*—A net profit of £1,573 has been made after payment of all capital charges.

**Fife:** *Interruption of Supply.*—A serious breakdown occurred last week to one of the turbo-generators in the power-house of the Fife Electric Power Co., at Townhill. The supply had to be discontinued for a short time, and there was considerable interruption of the local tramway services.

**Gloucester:** *Electricity Accounts.*—The result of the year's working of the Electricity Supply Department is a deficit of £106, after payment of all capital charges. This is partly accounted for by the extra capital expenditure incidental to the recent extensions, which are not yet being used to their full capacity, and the increased cost of fuel.

**Greenock:** *Electricity Accounts.*—A net profit of £5,204 has been made on the year's working at Greenock. The total income was £49,209, as compared with £46,150 for the previous year.

**Halifax:** *Electricity Accounts.*—The electricity accounts for the year ending March 31st, 1913, show the total income was £48,025, compared with £42,749 for the preceding year. The total units sold were 7,488,235 and 6,256,583, so that

the average price obtained per unit was 1'539d., compared with 1'640d. The surplus of income over expenditure amounted to £2,408, compared with £2,199. The costs of generation fell from 0'485d. per unit sold to 0'483d., and the costs of distribution rose from 0'107d. to 0'117d. Management and general charges fell from 0'109d. to 0'101d.

**Heywood:** *Bulk Supply.*—A provisional agreement is to be entered into for a ten-years' supply for this district by the Bury Corporation with the option of continuing for a further five years.

**Maidstone:** *Electricity Accounts.*—A surplus of £1,181 is reported on the electricity undertaking, in spite of a considerable increase in the cost of coal. The units sold for private supply have increased considerably, but the substitution of metal filament lamps for arc lamps for street lighting has caused a decrease in the supply for this purpose.

**Oulton Broad:** *Electricity Supply.*—The Oulton Broad Electricity Company has given notice of their intention to apply for a provisional order for the supply of electricity for all public and private purposes in the district. The company has already sent in a tender for street lighting.

**Portrush:** *Electric Lighting Order.*—The Provisional Order relating to the supply of electricity by the Urban District Council was passed on Tuesday by the House of Commons Committee on Unopposed Bills.

**Worthing:** *Electric Cooking in Camp.*—An electric cooking installation has been at work in the camp of the Church Nursing and Ambulance Brigade, and the camp is lighted throughout electrically.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

### Generating Stations, Sub-Stations, Mains, &c.

**Belfast.**—A Local Government Board inquiry is to be held early next month into an application for a loan of £35,000 for electrical purposes.

**Bury.**—The loan of £55,000, which, as stated in our issue of July 31st, is to be applied for, is to provide for the following plant:—Two rotary converters, £2,100; a third generating set for the Chamber Hall power station, £13,500; extension to buildings, £14,000; H.T. mains, £10,000; transformers, £4,000; L.T. mains, £5,000.

**Dublin.**—Tenders are invited for single-phase and three-phase meters. (See advertisement on another page.)

**Felixstowe.**—A Local Government Board inquiry was held last week into an application for a loan of £4,729 for extensions to the electricity works, including a 150-kw. Diesel set, a balancer, switchgear, and alterations to buildings.

**Manchester.**—Tenders are required for the supply and delivery of paper-insulated E.H.T. cables, 8-core telephone and 3-core pilot cable. Tenders by August 18th.

**Rochdale.**—Tenders are invited for a wet air filter and circulating water screens.

### Wiring

*The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.*

**Barnsley.**—New Town Hall.

**Chester.**—Additions to workhouse, Boughton Heath. Architect, J. H. Davies & Sons, 14 Newgate Street, Chester.

**Hunslet.**—Alteration to Nurses' Home. Architect, W. E. Richardson, Rothwell, Leeds.

**Letchworth.**—New hospital.

**London:** *L.C.C.*—Tenders are invited for an electric lighting installation at the Royal Hill Elementary School, Greenwich. (See advertisement on another page.)

FOR  
STEAM JOINTS  
USE

JOHN HUDSON & CO.'S SUCCESSORS, Mansell St., London, E.

**Islington.**—Extensions to postal stores. H.M. Office of Works.

**Manchester.**—New baths, New Quay Street.—Proposed Central Municipal School at Chorlton.

**Rugby.**—Tenders are invited for extensions to the electric lighting installation at the Rugby Co-operative Society's premises in Chapel Street. Tenders by August 18th. Particulars from W. H. Watson, Secretary.

**Sheffield.**—New premises for the *Sheffield Telegraph*.

**Stockport.**—New premises for Stockport Industrial Co-operative Society. Architects, Wrathmell & Blackshaw, St. Peter's Square, Stockport.

**Walsall.**—Tenders are invited by 25th inst. for electric lighting plant at Great Barr Hall and other buildings in Great Barr Park.

a varying amount to all girls who had been employed for three, five, and eight years. A special profit-sharing scheme was also put into force.

**Change of Address.**—Tetley & Co. (Falcon Works, Bedford Street, Greengate, Salford) have removed their offices to Exchange Buildings, 6 St. Mary's Gate, Manchester.

**Bankruptcies.**—W. R. Wedge, electrical engineer, of Northampton, has been adjudicated a bankrupt.

A first and final dividend of 1s. 4½d. is to be paid in the bankruptcy of Longdon & Cobb, Nottingham, and of 18s. 9d. in the £1 regarding the separate estate of W. Longdon.

The British Electromobile Co. is to be wound up voluntarily.

Mr. F. T. Johnson, Electrical Engineer, Cambridge, has been adjudicated a bankrupt.

## TENDERS RECEIVED AND ACCEPTED

**Bridlington.**—The tender of the Sturtevant Engineering Co. for a wet air filter (£115) has been accepted.

**Burnley.**—The tender of the Electrical Co. for 70 tramcar watt-hour meters mounted on special spring frames has been accepted.

The tender of the British Westinghouse Co. for turbo-alternator, &c., has been accepted. As the amount slightly exceeded the estimates, application is to be made to the Local Government Board for a slight increase in the loan.

**Falkirk.**—The tender of the Electrical Co. for polyphase meters with and without maximum demand indicators has been accepted.

**London: Hammersmith.**—The tender of the Electrical Co. for the supply of hour meters for the ensuing twelve months has been accepted.

**Loughborough.**—The tender of Clarke, Chapman & Co., £1,774, for a boiler has been accepted.

**Rotherham.**—The tender of Messrs. Chamberlain & Hookham for meters of 10 amperes capacity and upwards has been accepted.

**Stockport.**—The tender of Messrs. Bell Bros., Manchester, for grease-eliminating and water-softening plant, has been accepted.

## COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

**Manaos Tramways & Light Co.**—A surplus, after payment of debenture interest, &c., of £28,107 is reported. £25,725 is to be transferred to reserve and renewals account, and a 4 per cent. dividend is recommended, with £3,435 carried forward. There has been a considerable increase both in the private and public lighting connections, and the power load has increased about 100 per cent.

**Northampton Electric Light & Power Co.**—An interim dividend at the rate of 5 per cent. per annum is announced.

**The Waste Heat & Gas Electrical Generating Stations.**—An interim dividend at the rate of 5 per cent. has been declared.

**Oxford Electric Co.**—An interim dividend at the rate of 6 per cent. per annum is to be paid for the half year.

## NEW COMPANIES

**EDISON ACCUMULATORS**, 49 Old Bond Street, W. Capital £150,000. Manufacturers of and dealers in storage batteries of all kinds. To adopt an agreement with J. F. Monnot. First directors, Lord Montagu, Colonel H. C. L. Holden, A. L. Pearce, and J. F. Monnot.

**LEYBURN ELECTRIC SUPPLY CO.**—Capital £12,000.

## APPOINTMENTS AND PERSONAL NOTES

The salary of Mr. H. F. Ellis, Electrical Engineer, South Shields, has been increased from £400 to £450.

A Junior Assistant Electrical Engineer is required for the Far East. (See an advertisement on another page.)

An experienced mechanical and electrical engineer is required for a group of collieries. (See an advertisement.)

## MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. George Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £72 10s. to £73 (last week, £70 5s. to £70 15s.).

**Works Outing.**—On Saturday last over 300 employees of A. Reyrolle & Co. (Hebburn-on-Tyne) made a day's excursion to Edinburgh.

**Sunbeam Lamps.**—The goodwill and trade-mark of the Sunbeam Lamp Co. (in liquidation) has been purchased by the Armorduct Manufacturing Co., Ltd., Farrington Avenue, E.C.

**Cryselco, Ltd.**—The directors of Cryselco, Ltd. (Bedford), on the occasion of closing their works for the week for the August holiday, announced that in addition to paying everybody employed a week's wages, a bonus would be paid of

Cheques to be made payable to THE KILOWATT PUBLISHING CO., LTD., and to be crossed LONDON COUNTY AND WESTMINSTER BANK (Temple Bar Branch).

## SUMMARY

A SHORT article deals with the vexed question of "general conditions." (Page 476.)

A LARGE country house installation, where electricity is used for lighting, heating, vacuum cleaning, and pumping both for water supply and fire purposes, is described. (Page 477.)

A LETTER from Siemens Bros. Dynamo Works, Ltd., explains that the coming "Half-Watt" lamp will only be supplied in units of high candle-power for some time to come. Statements appearing in some of our contemporaries have implied that the lamps are to be obtainable in small units. (Page 477.)

THE design of isolating switches controlled from a distance is dealt with in our Questions and Answers columns. (Page 478.)

THE costs of operation of the street lighting systems in Chicago show that the system in use there of having tungsten lamps in opalescent bowls on old gas standards costs £1,720 per mile to instal, and £380 per annum to maintain. With flame arcs the corresponding figures are £1,875 and £860 to instal, and £348 and £255 to run, with underground and overhead distribution respectively. (Page 479.)

SOME particulars of closed circuit fire alarm systems for small and large installations for all classes of service, are set forth. (Page 479.)

A SHORT article deals with the award of contracts for the electrical equipment of the London & North Western and the South Western Railways. (Page 480.)

A DESCRIPTION is given under Telephony and Telegraphy of a continuously loaded telephone cable which has been laid between Vancouver and Victoria.—The Postmaster-General is prepared to continue the Hull telephone licence on certain conditions.—A net profit of £413,294 has been made by the Marconi Co. (Page 480.)

A PATENT specification by G. Lüdecke and the Brimsdown Lamp Works for a furnace in which the carbonising, decarbonising, and forming of metallic filaments may be carried out at one and the same time was published last Thursday.—Among the other patents is one for electromagnetic percussive tools by L. Schuler, and one for a loud-speaking electro-pneumatic telephone receiver by C. Stille.—Opposition has been entered to the grant of three patents to Julius Pintsch A.-G. for the manufacture of ductile tungsten filaments.—The patent relating to pull-chain switch lamp-holders granted to H. Hubbell and allowed to lapse has been restored. (Page 481.)

THE Report of the Select Committee on Motor Traffic recommends further power being given to the County Councils for the regulation of traffic subject to general control by a Traffic Branch of the Board of Trade. Responsibility for the increase of accidents is directly attributed to the motor-bus.—A clause in the Post Office Tube Railway Bill has been inserted in the House of Lords requiring the Postmaster-General to put the power supply to the railway up to competition of the supply companies.—The trolley omnibus system at Ramsbottom was opened for traffic last Thursday.—The loss of £2,865 on the Walthamstow Tramways is attributed to motor-omnibus competition. (Page 482.)

THE scheme of the Installation Department of the Sheffield Corporation has been referred to a special committee.—A deficit of £1,445 has been made on the Bath electricity undertaking, and a net profit of £337 has been made at West Bromwich. (Page 483.)

LOCAL GOVERNMENT BOARD inquiries are to be held at Batley (£8,206), Bingley (£7,000), Belfast (£35,000), Cardiff (£30,500), and Newport (£10,600). An application is also to be made for a loan of £12,000 at Heywood.—A turbo-alternator is required at Wimbledon; switchgear at the L.C.C. Greenwich station; and mixed pressure turbines and direct current generating plant at Edinburgh. (Page 483.)

SOME officially-attended experiments on wireless firing of explosives from a distance are reported from France, but are being received with some scepticism. (Page 483.)

## GENERAL CONDITIONS

THE differences between British electrical manufacturers and some buyers of electrical plant with regard to the General Conditions of tender still continue. In the short article, on p. 480, upon the contracts for the electrical equipment of the L. & N.W. and S.W. Railways, reference is made to an announcement in a contemporary that British firms refused to accept the General Conditions for the former contract, and did not tender. This, as we have said, is not the fact. British firms did tender, and the plant will be supplied by five firms—four British and one foreign. The award of the contract for the electrical equipment for the trains themselves was given to the Oerlikon Co. on price, and not as the result of any dispute as to the general conditions. Nevertheless, considerable soreness was felt owing to the drastic nature of these general conditions, a copy of which we have before us. The Chief Electrical Engineer to the Company, Mr. F. A. Cortez-Leigh, is designated as sole arbiter:—" . . . in all cases of difference of opinion between the Company and the contractors, the decision of the Engineer shall be final and binding upon all parties in all matters connected with the contract or any additions thereto." There are also many other onerous conditions, which we fear, however, are not uncommon in other similar sets of general conditions—for instance, holding the contractor liable for any expense he may be put to in consequence of errors in the specification or drawings, and a clause making the contractor "guarantee the Company harmless against all accidents, damages, claims and losses which may occur, or to be incurred, or claimed by reason of . . . any cause which in the opinion of the Engineer shall have been within the control of the contractors . . . notwithstanding any instructions which have or have not been given by the Engineer. . . ."

In such cases it is not unusual for contractors to send in tenders, even if they are not willing to accept the general conditions as they stand, the tenders being only conditional upon a subsequent agreement being arrived at as to a modification of the general conditions. This, we believe, has recently been the practice of the firms belonging to the British Electrical and Allied Manufacturers' Association, and it has been confidently stated to us from a source that should be exceptionally well informed, that in practically no recent

case has any important municipal electrical contract been awarded out of the country for the sole reason that the British firms have adopted this course when tendering. The placing of some recent large municipal contracts with foreign firms, instead of with British firms, has, our informant, contends, been invariably because the foreign firm has quoted a lower price. Certainly, it would be hard to credit that these disputes as to the wording of the General Conditions should be carried to such a pitch that the purchaser would be content both to pay more for his plant and to buy it abroad.

It is to be regretted that the "Model" General Conditions have not long ago been agreed upon. It is now a considerable time since a code was agreed between a Committee of the Institution of Electrical Engineers (upon which were representative consulting engineers and delegates of the I.M.E.A.) and the B.E.A.M.A., but apparently the Council of the Institution was loth to pass this as final until the I.M.E.A. had agreed to accept it. We understand from the Secretary of the B.E.A.M.A. that a further revised code (so far as it referred to the points in dispute), was then agreed upon between the I.M.E.A. Council and the B.E.A.M.A., and this has, as our readers know, already been discussed *in camera* on two occasions (at the Annual Convention, and again last month) by the members of the I.M.E.A. As the second of these meetings was held as long ago as July 11th, and no announcement has yet been made, it is reasonable to assume that the code agreed upon by the I.M.E.A. Council has not been ratified by the membership.

We have it on the authority of a high official of one of the largest manufacturers of electrical plant in this country that the differences of opinion as to General Conditions are usually concentrated upon three points, viz., disputes and arbitration, consequential damages, and terms of payment. On the first of these there should be easy compromise, once the untenable position is abandoned that the purchasers' engineer should be sole arbiter. On the second point it is almost safe to say that the majority of contractors aim chiefly at having their liability for consequential damages defined in such a way that they can insure against it; and the question as to terms of payment is, after all, merely a business bargain, and absolutely standard percentages to apply to all contracts should not be held to be a necessity.

**WELL-INFORMED TOURIST:—**Those kites help to pull the train up the steep hills. If the wind drops suddenly, they hook the thing on to the wire above so that the train doesn't run back, and the electrical compressors under the locomotives are then started to supply compressed air for the kites.

## A COUNTRY HOUSE INSTALLATION

VARIED applications of electricity for domestic uses are in evidence at Somerton House, Co. Dublin, the residence of Mr. T. K. Laidlaw, which has recently been reconstructed. Electric light is used throughout the house, farm, and stable buildings, and current is also utilised there for electric radiators and power appliances. Electric power is used to drive a stationary vacuum cleaning plant for cleaning carpets, floors, and furnishings; also for pumps to raise domestic and rain water to roof tanks in the house and supply fire service hydrants. Electric bells and telephones are employed throughout the house and outside buildings.

The generating and storage plant is accommodated in an outbuilding, and includes a horizontal oil engine by Tangye, Ltd., capable of developing a maximum of 22 b.h.p. and a constant working load of 19 b.h.p. with crude oil of 0.8 specific gravity when running at 210 r.p.m. The engine is fitted with a compressed-air starter. A storage tank to accommodate 5 tons of fuel is provided, and is buried in the ground. The dynamo, by the British Thomson-Houston Co., is belt-driven, with an output of 8 kilowatts at 100 to 150 volts. The battery, manufactured by the Tudor Company, consists of 56 cells contained in glass boxes, and has a discharge capacity of 480 ampere hours for 10 hours. Tanks for acid and distilled water are fixed on wall-brackets, and connected to flexible piping used to fill the cells as required. The switch-board in the power-house is made up of enamelled slate slabs resting on channel iron supports with iron fixtures, and provided with an expanded metal door at one end.

Underground vulcanised bitumen cables are led from the main switchboard to the house, stables, and domestic water and fire service pumps. They are laid about 2 ft. below the surface of the ground in creosoted wood troughing fitted with porcelain bridge supports filled in solid with pitch, and covered with tiles. For the branch wiring vulcanised india-rubber conductors of 2,500 megohm grade are contained in solid drawn steel tubing carried behind walls and ceilings, except in servants' quarters and outbuildings, where the tubing is exposed and spaced out from the walls by brass hold-fasts. The tubing throughout is fixed to the iron cases of distributing boards by lock nuts, so that the whole containing system is continuous, and also efficiently connected to earth. The electric light fittings harmonise with the interior decorations, and were supplied by Messrs. Perry and Messrs. Osler. The wiring for electric bells and telephones is of 1/20 S.W.G. 300 megohm conductors run in split Simplex tubing with slip couplings.

The stationary vacuum cleaning plant by the Scottish Vacuum Cleaner Co., is placed in a basement apartment. It includes a rotary pump belt driven by a 2 b.h.p. motor; 2 in. piping is led to nozzles fixed to wall skirting boards on the several floors.

The supply of water for general use is obtained from a well by a petrol engine-driven pump. This source of water supply is also available for fire-extinguishing purposes, the pressure being augmented by an electric turbine pump connected to fire mains led around the house, and fitted at intervals with hydrant valves for hose attachment. Rain water is collected and stored in an underground tank of 50,000 gallons capacity, and is raised therefrom by an electric centrifugal pump operated by automatic switches to two tanks in the roof space of the house. The water supply pipe system is arranged so that the spring water is led direct to the taps, &c., from an outside storage tank, and rain or spring water may be used to fill either or both house tanks, thus providing against the possibility of a scarcity of water due to shortage in the former supply. An artesian well is now being sunk in the grounds, and it is expected that a better supply of drinking water will be obtained from this source, and provision has been made for it being raised to these tanks by the existing pumping plant.

The rain-water pump is capable of lifting 1,500 gallons per hour, and is direct connected to a 2 b.h.p. shunt-wound motor.

A turbine pump and direct-coupled 6 b.h.p. shunt-wound motor, by Mather & Platt, at 1,500 revolutions per minute, is erected in the pump-house at the stables alongside the rain-water pump. The switch panels for both these pump sets include line and starting switches with no-volt and overload release, shunt regulator, and ammeter, all enclosed in cast-iron cases with glass fronts and mounted on iron framework. The fire pump is designed to allow three jets of water being thrown at one time to a height of 60 ft. from hydrants accommodated in ground boxes connected to the 4 in. diameter spigot and socket cast-iron pipe main led around the house. Air

valves are fitted to this piping where necessary, and a sluice valve with wash-out cock allows of the mains being emptied during frosty weather, although, as a rule, they are kept full of water. A very complete system of hot-water heating is provided.

The whole of the electrical work was carried out by Messrs. Brash & Russell, Glasgow, under the supervision of the consulting engineers, Messrs. J. E. Sayers & Caldwell.

## CORRESPONDENCE

## THE "HALF-WATT" LAMP.

To the Editor of ELECTRICAL ENGINEERING.

DEAR SIR,—In order to correct certain erroneous rumours which have been circulated during the past few weeks on the subject of the new "Half-Watt" lamp, we shall be glad if you will inform your readers that the lamp in question will, at any rate, for some considerable time to come, only be supplied in units of extremely high candle-power to compete with high-pressure gas arcs for street lighting, &c., and, of course, electric arc lamps.

It is probable that such "Half-Watt" lamps will be available in commercial quantities during the present year, and we hope before long to have an opportunity of demonstrating the lamp to members of the Press.

The new lamp is of particular interest as it embodies certain novel processes of manufacture, not hitherto applied to electric lamps.

Yours faithfully,

SIEMENS BROTHERS DYNAMO WORKS, LTD.

Incandescent Lamp and Fittings Dept.,  
Tysen Street, Dalston, N.E.

[These rumours were dealt with in an article in our issue of July 17th (p. 416), in which the correct facts mentioned in the above letter were stated, and the correct position was again emphasised in the cartoon which appeared in our issue of July 24th. As the incomplete statements and erroneous conclusions of some of our contemporaries have given rise to a considerable amount of uneasiness in various quarters, we have pleasure in publishing the facts once more in the above letter.—Ed., E.E.]

## CATALOGUES, PAMPHLETS, &amp;c., RECEIVED

**LIGHTING SUPPLIES, &c.**—A pocket size nett price list has just been issued by Baxendale Brothers (96 Whitechapel, Liverpool). Among the items making up the list are fans, "Sanitas," hot and cold air douches, cables of various sizes and grades, conduits, fittings, arc carbons, &c. There is also a selection of bells, bell wires, and primary and secondary batteries.

**DYNAMOS AND MOTORS.**—Particulars and illustrations of "Castle," W. type motors and dynamos are contained in a recent catalogue issued by J. H. Holmes & Co. (Newcastle-on-Tyne). Included are dynamos for cinematograph lanterns, low pressure dynamos, &c.

*Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."*

**ACID-PROOF SILICA LAMPS.**—A leaflet descriptive of the acid-proof silica lamps, for direct current, recently introduced by the Westinghouse Cooper Hewitt Co., Ltd. (80 York Road, King's Cross, N.), has just been issued. The efficiency is stated to be 0.22 watts per candle, while an earthenware casing is employed which makes a tight joint with the globe. The interior being thus protected from corrosive vapours, the lamp is of particular value in chemical and galvanising works, and others of a like nature.

**Ontario Hydro-Electric System.**—It has been decided to enlarge at once the Niagara Falls transformer station of the Hydro-Electric Power Commission of Ontario, and to double the line between Dundas and Niagara Falls.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,352.

I HAVE recently become responsible for laying air space telegraph and telephone cables, and should be glad to have some information on the following points:—(1) Is dessicating apparatus absolutely necessary? (2) Give a design for a really accessible test box having high insulation, for use in railway signal boxes. (3) What is a satisfactory way of securing a lead-covered cable when it has to be carried straight up a wall? (4) Is any harm likely to accrue if a 4-in. sag is allowed in an armoured cable supported on hooks 6 ft. apart? (5) What is a satisfactory form of lightning protector?—"POTHEAD."

(Replies must be received not later than first post, August 28th.)

### ANSWERS TO No. 1,350.

It is required to operate three 20,000-volt isolating switches simultaneously by means of fixed handle and link gear. The handle will be about 9 or 10 ft. away from the switches. Explain how you would do this, giving approximate dimensions of the apparatus in a sketch. The device must be mechanically and electrically sound, as the switches are not for a laboratory, but for use under the worst conditions. The gear must not be expensive to construct.—"ABSONDERN."

The first award (10s.) is given to "W. R." for the following reply:—

The sketches in Fig. 1 show one method of operating the three switches simultaneously. It has here been assumed that the switches will be mounted vertically. As the con-

FIG. 1.

struction of the operating gear is dictated principally by the insulation requirements, it is important that there should be

ample creeping distance between poles and to earth. The insulators should be of glazed white porcelain, and although the overall dimension given for the insulators could be reduced by using the corrugated type, it is found advantageous in practice to adopt the smooth type, principally on account of the greater ease in keeping them clean. It will be seen from the sketch that a steel piece is rivetted to each of the switch blades (see Fig. 1), and connected by a short steel coupling-rod to the top side of the insulators, the rods being "ragged" at the end, and cemented in the insulators which are grooved inside. Steel studs are secured in the bottom side of the insulators in a similar manner, and connected to a cross-coupling of light steel angle, this construction allowing individual adjustment of the switches. The cross-coupling angle is operated by two steel rods (gas piping can be used) from the fixed handle. The

FIG. 2.

handle gear consists of a bobbin-shaped wooden handle mounted horizontally on a steel spindle which connects the two coupling-rods to the two side-links, these side-links at the other end being carried by two brackets. A stop-pin should be fixed to the brackets to act as a stop for the handle when in the "off" position, thus obviating any risk of shock to the switches themselves due to rough handling. The metal-work of the handle-gear should, of course, be efficiently earthed. It is important that the switches should be of strong mechanical construction apart from the actual current to be carried, and barriers of slate or other suitable material should be fixed between switch-poles.

The dimension given between poles can be varied to suit requirements, though a minimum of 6 in. (in air) should be allowed between live parts of different poles.

The second award (5s.) is made to "N. G. W.," who writes as follows:—

No particulars are given of the current the switches are to carry, but it is assumed that it is comparatively small, say 150 to 200 amps., and that therefore the dimensions of the switches will be decided by the voltage and by mechanical reasons. The sketch in Fig. 2 is to scale, and indicates the approximate dimensions. It is assumed that the switches can be mounted on a wall, and that the handle-gear can be mounted below them. Also that the main point concerning which information is desired is the coupling of the handle-gear to the switches, and that it is an advantage if the handle-gear can be adapted to standard switches. Suffice it to say, regarding the switches themselves, that the centres from top contact to hinge should not be less than 15 ins., and the insulators should give a sparking distance of about 12 ins. With switches of this size the blade should be of the "stayed" type. That is, the actual blade "A" should be supported by stay-straps "B." These can be of wrought-iron, and should be hinged concentrically with the blade. To each pair of stays should be rivetted a pair of levers "C" provided with a pin coupling to them a connecting rod "D." This rod should be made of good, sound teak, thoroughly impregnated. It should be strengthened at the top by a pair of wrought-iron plates, one screwed each side, and should be fitted at the bottom with a wrought-iron strap into which the coupling-rod "E" can be screwed and locked with a nut. The other end of the coupling-rod is provided with a device "F" pinned to a lever "G." The three levers are keyed to a common shaft "H," which is provided with three bearings "J" and the handle-lever "K." The gear should be

SPECIFY

**IGRANIC**

Electric Controlling Devices

**IGRANIC ELECTRIC CO. LTD.**

(PROPRIETORS OF ADAMS MANUFACTURING CO. LD.)

147, Queen Victoria St., London, E.C.

Works: BEDFORD.

SEE ANNOUNCEMENT ON PAGE 21.

adjusted so that when in the "on" position the levers "G" just pass the dead centre and come up against a stop, so that there is no danger of the switches falling out or being forced out by magnetic action. Also if this is done there is no danger of the switches when "off" falling into the "on" position. The use of the impregnated-wood connecting-rod provides a very simple and efficient coupling, which can be made of length to suit the circumstances, and enables the metal parts of the driving-gear to be kept well away from the electrical connections.

**ANSWERS TO CORRESPONDENTS**

WAGLER.—Your reply came too late; try and catch the post next time. Thanks for your kind expressions of appreciation.

**FIRE ALARM SYSTEMS**

MANY modifications of the Siemens "closed-circuit" fire-alarm system are set out in new catalogues from Siemens Bros. & Co., Ltd. (Woolwich, S.E.). The fire-alarm boxes are connected in series with a current flowing continuously between them and the central fire station. For those cases where not more than 120 boxes are required, the indicator at the central station may be a graduated dial and pointer indicating the number of the box originating the call. At the same time, an alarm bell rings until the indicator has been restored to normal. Should the line wire become

injured, a definite signal is given at the station until the fault has been remedied. Fire calls can, however, still be received. The alarm boxes themselves are robust and well insulated, as may be seen from Figs. 1 and 2, which show one design in which is a telephone equipment in a separate locked compartment for police or ambulance work, &c. The clockwork mechanism which transmits the code call may be obtained to send a number of calls may require rewinding without rewinding, or it after each call. Provision is made to prevent the glass door being closed unless this operation is carried out. The dial apparatus at the station consists of

FIG. 1.—FIRE ALARM CALL BOX (CLOSED).

a well-made case, with hinged back and glass front. At the top is a telephone set with automatic cradle, and a telephone and fault bell. Inside is the dial, signal annunciator disc, relay pin controlling the dial mechanism, and a milliammeter. There is also the restoring mechanism and broken wire switch. The latter is used to convert the system temporarily to open-circuit working. Should a second alarm box be operated before the pointer has been replaced, it can be arranged that this call be transferred to a reserve dial. Permanent records may be obtained by the use of a Morse inker or punching register.

Simple hand-operated or automatic arrangements for efficiently calling out the entire brigade or certain members of it may also be supplied.

A development of this system is that known as the Siemens "Morse" system, which we learn is installed in over 100 cities and is approved and used by the British and other Governments. By an ingenious arrangement of the switchboard it is possible to receive simultaneously and without mutual interference calls from eight different boxes. It is easy, also, to record automatically the date, time and origin of every call. Another system is the "Perforator" system, especially intended for those situations where a large number of boxes

are necessary, but where many simultaneous calls are not expected. The greatest development of all is the "Automatic Repeating" system, in which all alarm calls are concentrated

FIG. 2.—FIRE ALARM CALL BOX (OPEN).

at the central station, and at the same time repeated to all sub-stations. Simultaneous calls may be recorded, and in this, as in the other systems, ample facilities are provided for testing and repair.

**COST OF THE STREET LIGHTING IN CHICAGO**

SOME interesting figures relating to the cost of the new street lighting in Chicago (*ELECTRICAL ENGINEERING*, Vol. VIII., p. 581, Oct. 24th, 1912) were recently given by Mr. R. Palmer, the City Electrician. According to the *Electrical World* (New York), when the new contract was entered into in October, 1910, there were 12,200 street arcs, and up to the present time 4,000 of the 10,000 additional 10-ampere flame arcs have been installed. The price paid for the energy used is \$15 (£3 3s.) per h.p.-year of 4,000 lamp-hours, or approximately 3d. per kw.-hour.

To light one mile of street with twenty-three flame arcs costs, with underground distribution, \$9,000 (£1,875), and with overhead distribution, \$4,000 (£860). These figures include sub-station and distributing costs. Where the system of underground distribution and tungsten lamps in opalescent globes on the old gas posts has been installed, the cost has come to about \$8,000 (£1,720), using seventy-five staggered on both sides of the street, and about 150 ft. apart.

Flame arcs on underground circuits cost in 1912 \$39.91 (£8 6s.) a year to maintain. To this should be added an interest charge on investment of \$19.16 (£4), and a depreciation charge of \$13.67 (£2 16s.), making the total yearly cost, according to Mr. Palmer's figures, \$72.74 (£15 2s.) per lamp. On overhead circuits the interest and depreciation costs are lower, bringing the total yearly cost down to \$54.57 (£11 7s.). The most expensive form of electric street lighting is the underground distribution system with tungsten lamps. The cost per unit for maintenance is only \$13.86 (£2 15s.), but allowing for interest and depreciation this comes to \$24.27 (£5 1s.) per lamp per annum. Thus, per mile of street the cost is \$1,820 (£379), compared with \$1,673 (£348) for flame arcs on underground circuits, and \$1,255 (£255) for flame arcs on overhead circuits.

Attention has been given recently to the lighting of the 625 street crossings under the elevated railways, or subway crossings, as they are called. The railway companies will be forced to instal and maintain lamps in 275 of these subways, the city being required to light the remaining 350. After an investigation a standard of one 16-c.p. lamp for each 400 sq. ft. of inclosed subway area was decided upon as sufficient. The railway companies have been trying to get the area of 400 sq. ft. increased to 800 sq. ft.

## THE LONDON & NORTH WESTERN AND THE SOUTH WESTERN RAILWAY CONTRACTS

A LONG letter and an editorial paragraph on the contracts for the electrical equipment of the L. & N.W. railway suburban lines appeared in *The Times Engineering Supplement* last week, in which it is erroneously stated that the Oerlikon Co. received the contract for the generating plant, and further hinted that the British manufacturers refused to tender for the contract on account of the "general conditions" accompanying the specification. We are in a position to inform our readers that both these statements are absolutely incorrect.

The London & North Western Railway, we understand, originally obtained the equipments for four electric trains from Siemens Brothers Dynamo Works, but, after inviting tenders for the electrical equipment of the lines now being "electrified," awarded the contract for the electrical equipment of the rolling stock to the Oerlikon Co. The trucks and bodies are being made by the Metropolitan Amalgamated Carriage & Wagon Company. For the power house, however, Westinghouse-Siemens turbine sets were ordered; and B.T.-H. rotary converters were chosen for the sub-station equipment. It is true that exception was taken to some of the "general conditions" by the firms tendering, but in some, if not in all, cases a compromise was arrived at.

In the case of the South Western Railway, the order for the equipment of the trains was given to the British Westinghouse Company; Dick, Kerr & Co. supply the generating plant; and the sub-station equipment is, as in the case of the L. & N.W. Railway, to be carried out by the B.T.-H. Co.

### TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

The *Electrical News* (Toronto) contains an interesting description of a continuously-loaded telephone cable made by W. T. Henley's Telegraph Works Co., Ltd., of London, and laid by the British Columbia Telephone Co. between Point Grey, near Vancouver, and Newcastle Island to develop the telephone traffic between Vancouver and Victoria (B.C.). The length of the cable is 28.3 nauts, and it is continuously loaded. Each of the four conductors consists of a central wire 0.082 in. diameter, surrounded by twelve smaller wires each of 0.0285 in. diameter, giving the composite conductor a diameter of 0.139 in., and a weight of 300 lb. per naut. A soft iron wire, 0.012 in. diameter, is wound closely round this, making seventy turns per in. The conductor is then covered with gutta percha, having a weight of 300 lb. per naut, and the four cores are stranded round a centre of yarn with yarn worming between the cores. The whole is covered with brass teredo tape and armoured with fifteen galvanised steel wires 0.192 in. diameter, which are embedded in yarn and protected by two layers of yarn and preservative compound. The whole cable has a diameter of nearly 2 in. and weighs 8 tons per naut. The electrical constants of each core per naut are as follows:—Resistance, 4 ohms; capacity, 0.35 m.f.; dielectric resistance, 250 megohms after one minute's electrification at 75° F. The attenuation constant is about 0.019 per naut. of cable at 800 cycles per sec.

The cable is worked with a phantom circuit, so that it can be used for three conversations simultaneously. According to our contemporary, a continuously-loaded type of cable was adopted in place of the coil-loaded pattern used for the Anglo-Belgian cable, owing to the fact that it is laid in much deeper water, and that the latter type was not considered to be safe for the deep waters of the Gulf of Georgia. The maximum depth at which the cable is laid is about 1,300 ft.

A decision has been given by the Postmaster-General regarding the application of the Corporation to continue the control of the Hull telephones. It is understood that the

## PATENTS.

*Small Prepaid Advertisements with regard to Patents, &c., are inserted on this page, facing our Patent Record, at 1d. per word (minimum 5s.); three insertions for the price of two. Rates for displayed and card advertisements on application.*

*Advertisement matter, accompanied by a remittance, should be addressed to the Kilowatt Publishing Co., Ltd., 203 Temple Chambers, London, E.C.*

**TO ELECTRIC APPARATUS MANUFACTURERS.**—The owners of British Patent No. 10,793 of 1909, relating to "IMPROVEMENTS IN OR RELATING TO THE PRODUCTION OF ELECTRIC CURRENTS," are desirous of entering into negotiations with one or more firms in Great Britain for the purpose of exploiting the above invention, either by sale of the Patent outright, or by granting licenses to manufacture under royalty. Inquiries should be addressed to MESSRS. AEBL & IMRAY, Chartered Patent Agents, 29 Southampton Buildings, London, W.C.

**PATENT.**—The proprietors of British Patent No. 17,331 of 1908, relating to IMPROVEMENTS IN REVERSIBLE GALVANIC BATTERIES, desire to enter into arrangements by way of license or otherwise, on reasonable terms, for the purpose of developing and practically working the same in this country. Inquiries should be addressed to W. P. THOMPSON & Co., Chartered Patent Agents, 285 High Holborn, London, W.C.

The owners of British Patents Nos. 25,473, 25,397, and 6,402, all of 1910, entitled, respectively, "IMPROVEMENTS IN AND RELATING TO REPULSION MOTORS OPERATING AS GENERATORS," "IMPROVEMENTS IN AND RELATING TO THE EXCITATION OF INDUCTION DYNAMO ELECTRIC MACHINERY," and "IMPROVEMENTS IN AND RELATING TO THE CONNECTION OF SINGLE-PHASE MOTORS TO POLYPHASE CIRCUITS," are desirous of disposing of the patents or entering into working arrangements under license or otherwise with firms likely to be interested in the same.

Copies of the patent specifications and full particulars can be obtained from, and offers made (for transmission to the owners) to, MARKS & CLERK, 57 & 58 Lincoln's Inn Fields, London, W.C.

### John E. Raworth,

Queen Anne's Chambers, Chartered Patent Agent.  
36, Broadway, Westminster, London, S.W.

### REMOVAL.

MR. J. G. LORRAIN, M.I.E.R., M.I.Mech.E., Chartered Patent Agent, has removed his office from Norfolk House, Norfolk Street, Strand, W.C., to  
**Staple Inn Buildings, High Holborn, London, W.C.**

### APPOINTMENTS VACANT & WANTED.

**YOUNG MAN** with practical mechanical experience in telegraph and telephone repairs wanted for West Indies. Good climate. Three years' engagement; passage paid both ways. State age and salary expected. Apply with copy of testimonials to RAILWAY, c/o A. F. SHARP & Co., Advertising Agents, Glasgow.

**ADVERTISER.**—Six years' varied Mechanical Experience, and four years' Electrical (now Assistant Engineer on Staff of large Power Co.), desires responsible situation. Highest references, past and present. Address, A. UNIT, 192 Newport Road, Cardiff.

**CARTOONS FROM "ELECTRICAL ENGINEERING."**—In response to numerous requests for the original drawings of the Cartoons published in *ELECTRICAL ENGINEERING*, we have made arrangements by which these may be purchased by readers at £1 ls. each.

Reproductions of any Cartoons that have been published in *ELECTRICAL ENGINEERING*, neatly framed in plain oak frames, are also obtainable at 3s. 6d. each.

Books of Cartoons from October, 1910, to September, 1911. Price 8d. (post free, 9d.).

Orders (accompanied by a remittance) should be sent to the **KILOWATT PUBLISHING Co., LTD.**, 203 Temple Chambers, London, E.C.

# "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

## Specifications Published August 14th, 1913

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in *italics> indicate communicators of inventions from abroad.*

18,184/12. **A.C. Percussive Tools.** L. SCHULER. The current is controlled by a synchronous interrupter so that the tool magnet coil is fed during two consecutive half-waves of pressure for a time, so that the magnetic field is produced and disappears. No sparking occurs when the current is stopped or weakened during the return of the armature. Five figures.

19,763/12. **High-frequency Currents for Wireless.** W. DUBILIER. A constructional form of the electrodes required for the system described in Specification No. 11,091/12 (ELECTRICAL ENGINEERING, Vol. VIII., p. 538, September 26th, 1912). A number of electrodes are moved by either rotation, reciprocation, or oscillation across other fixed electrodes, so that the arc is first made, and later suddenly broken. The faces of the electrodes are kept substantially parallel to the line of motion. Six figures.

20,446/12. **Telpher System.** J. E. POLLAK (*Elektromotoren-Werke Hermann Gradenwitz, Germany*). Rotary switches are operated mechanically by passing cars, and electromagnetically released so that separate block sections of the power contact conductor are cut in and out of circuit. The switch can take up a third position during the passage of a car to cut in an auxiliary section at the rear of the block section through a resistance, so that a following car may proceed slowly. Three figures.

21,351/12. **Loud-speaking Telephone Receiver.** R. LAGUS. The distance between the receiver and the microphone is adjustable, and in the cover of the microphone around the usual large central hole, small conical holes flared towards the membrane are provided. The carbon granules behind are subdivided into a corresponding number of independent parts. Four figures.

21,761/12. **D.C. Dynamo Field Construction.** B.T.H. Co. (*G. E. Co., U.S.A.*). A portion of the exciting windings are situated in slots in the interpolar space, which, in addition, carry compensating windings. The mid-interpolar tooth acts as a commutating pole. Two figures.

2,146/13. **Fixing Terminals to Aluminium Conductors.** L. W. CHUBB. A copper conductor is welded to the aluminium conductor so that the terminal may be soft-soldered to this. Five figures.

6,952/13. **Furnace for Tungsten Filament Manufacture.** G. LÜDECKE and BRIMSDOWN LAMP WORKS. With the object of carbonising, decarbonising, and forming filaments from the raw state in one operation, a cylinder of metallic tungsten or molybdenum is provided within the heated zone of a furnace as described in Specification No. 8,996/11. Rods of tungsten or molybdenum are arranged in the form of a cage, and serve to conduct the heating current. The cage is placed in a furnace shaft of copper or nickel, and the filaments to be treated are introduced into the cage through the top of this shaft, which may then be closed. Provision is made for the expansion of the cage by providing a mercury contact at the bottom of the cage. The furnace is water-cooled. Three figures.

9,644/13. **Loud-speaking Telephone Receiver.** C. STILLE. An electro-pneumatic sound-box is described in which a suspended slotted plate is moved to and fro above another similar plate by an electromagnet actuated by the received currents, so that the air escaping is regulated in accordance with them. Three figures.

13,911/13. **Large Traction Magnets.** MAGNET-WERK GES. Electro-magnets for lifting heavy loads have a fan built into the frame to cool the windings. One figure.

14,214/13. **Short-circuiting Lightning Arresters.** SIEMENS & HALSKE. A short circuit for lightning arresters is actuated by metals with different coefficients of expansion, so that heat due to an excessive current causes a bending so as to effect the short circuit, which is, however, automatically removed when the current falls. One figure.

## Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free. Summaries of some of the more important of these patents will appear in our next issue.

**Arc Lamps:** MOUL (*Korting & Mathiesen A.-G.*), 11,704/13.  
**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** SIEMENS BROS. DYNAMO WORKS (*Siemens Schuckert*). [Driving ring-spinning and doubling frames] 18,013/12; SMITH [Adjustable cable sling suspender] 18,542/12; HOWARD [Cable

armouring] 24,237/12; ROUTIN [Synchronous running of motors] 24,751/12; LOEWENTHAL [Insulating layers on cables] 27,651/12.

**Dynamos, Motors and Transformers:** BARTSCHI [Magnetos] 19,963/12; LEITNER [Variable-speed dynamos for starting internal-combustion engines, &c.] 23,273/12; KELLER-DORIAN [Induction generators] 1,100/13.

**Electrometallurgy and Electrochemistry:** SCOTT [Nitrogen-fixing furnaces] 14,871/12; DUNLOP TYRE Co. and KEEGAN [Wheel-rim welding] 17,583/12; HADDAN (*Cleveland Welding & Mfg. Co.*) [Welding] 17,749/12 and 29,999/12; MOLLER [Separating bodies in suspension from gaseous fluids] 17,840/12; HEROUT [High grade pig-iron] 25,974/12; DU BOIS [Electrolysis] 1,420/13 and 1,439/13; DEKKER [Deposition of metals] 7,328/13.

**Ignition:** SIMMS and SIMMS MAGNETO Co. [Automobile starting] 9,924/12.

**Instruments and Meters:** SIEMENS & HALSKE [Housing recording strip of electro-cardiographs] 7,846/13; ARON ELEKTRICITÄTSSÄHLERFABRIK GES. [Bearings] 11,277/13.

**Switchgear, Fuses and Fittings:** TUCKER [Fuses] 19,642/12; RAILING STRACHAN and HOADLEY [Current limiters] 23,917/12; TAYLOR [Relays] 26,351/12; SMITH [Adapter-holder] 26,651/12; WORRELL [Locking bayonet-type lamps to their holders] 2,139/13; WADE (*Voigt & Haeflner A.-G.*) [Luminous indicator for switches] 7,581/13.

**Telephony and Telegraphy:** CHABEAULT [Transmitting to a distance and recording theatrical performances, &c.] 1,444/13; GRAHAM and RICKETS [Telephone systems] 2,610/13; CEREBOTANI [Printing telegraphs] 9,833/13.

**Traction:** THOMAS and THOMAS TRANSMISSION, LTD. [Power distribution] 17,130/12; VAN DAALEN and SCHREIBER [Control of electrically-operated, self-propelled vehicles] 17,306/12; FIRTH and LEAKE [Signalling] 25,991/12; JOHNSON and THORROWGOOD [Signal control] 26,879/12; ANDERSON [Trolley wheels] 3,371/13.

**Miscellaneous:** HUDSON [Miners' safety lamps] 14,385/12; ROOTHAN and FERBANTI, LTD. [Resistances] 17,980/12; COCARD [Remote operation of valves, &c.] 27,979/12; GRAY [Gyrostatically-controlled moving body] 29,530/12; KRUPP A.-G. GRUSONWERK [Magnetic separator] 4,595/13.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Arc Lamps:** SIEMENS SCHUCKERT [Regulating light intensity] 17,086/13.

**Distributing Systems, Cables and Wires, &c.:** GILES [Safety devices for cables] 15,951/13.

**Electrometallurgy and Electrochemistry:** SOC. GEN. DES NITRURES [Furnace resistance elements] 12,837/13.

**Instruments and Meters:** SOC. D'ELECTRICITÉ MILMELIOR [Indicating recording and controlling devices] 16,641/13.

**Switchgear:** SIEMENS & HALSKE [Relay] 17,137/13.

**Telephony:** SIEMENS & HALSKE [Automatic and semi-automatic circuits] 14,487/13; ERICSSON [Automatic switch] 17,038/13.

## Opposition Entered to Grant of Patents

5,026/12, 5,027/12, and 5,028/12. **Ductile Tungsten Filaments.** J. HUBERS (*Julius Pintsch A.-G.*). The processes claimed are for the production of ductile tungsten filaments by first alloying a tungsten compound with an oxide of thorium or other rare earth metal. (ELECTRICAL ENGINEERING, June 26th, p. 386.)

## Grant of Patents Allowed

15,669/11 and 15,679/11. **Gyro-compass.** E. A. SPERRY. See ELECTRICAL ENGINEERING, Vol. VIII., p. 550, October 3rd, 1912.

## Restoration of Lapsed Patent

15,801/01. **Pull-chain Switch Lamp-holder.** H. HUBRELL. This patent which was allowed to lapse. (ELECTRICAL ENGINEERING, March 20th, p. 166.)

## Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** A. E. TANNER [Sectionalised distribution systems in which if a section becomes faulty it is automatically cut out, and both ends earthed by special cut-outs] 10,080/04; SOC. MATHELOT ET GENTILHOMME [Synchronous rotation of motors driving a phonograph and cinematograph] 8,865/08, 9,371/08, and 9,372/08.

**Traction:** R. BARON [Pressed or stamped trolley heads] 8,846/05.

**Miscellaneous:** J. WILHELM [Electrically-driven coal-whips or hoists] 9,969/04.

general nature of the conditions laid down are that the Postmaster-General is prepared to continue the licence of the Corporation provided they will take over the plant of the National Telephone Co. at the price at which the Post Office purchased it, and also will make arrangements for the voluntary transfer of the staff. This offer is being considered by the Corporation.

In answer to a Parliamentary question as to the efficiency of the telephone service, the Postmaster-General stated that on the result of about 50,000 secret observations it had been ascertained that for the first six months of 1911 and 1913 the following figures had been obtained:—Average speed of answers to calls (1911), N.T. Co., 5·8 sec., P.O., 5·1 sec.; (1913), P.O. combined system, 5·1 sec. Similarly, effective calls formed 65·9, 68·7 and 70·5 per cent. respectively of the total number of calls. "Engaged" calls formed 18·6, 18·9 and 17·4 per cent. of the total calls, while "no-reply" calls formed 4·5, 2·5 and 4·1 per cent.; and "cut-offs," 0·7, 0·4 and 0·6 per cent. respectively of the total number of calls.

In the House of Commons last week a return was ordered to be issued of patents in respect of which royalties will be payable under the contract of the Government with the Marconi Co., the dates when such patents were granted, the areas in respect of which they run, and the dates when they expire in the ordinary course.

The annual report of Marconi's Wireless Telegraph Co. records a net profit of £413,294, as compared with £141,717 for 1911. In view of a part of this profit having been derived from the realisation of shares, the directors are creating a reserve fund, to which they have apportioned £100,000 out of the profits. A 17 per cent. dividend is to be paid on the preference shares, and 20 per cent. on the ordinary shares, with £146,726 carried forward. It may be remarked, however, that in view of the high price of the ordinary shares, this dividend represents a net yield of about 6 per cent. The directors state in the report that they do not believe that the altered conditions of the contract for the Imperial chain of stations will prove of any disadvantage to the Company, and with regard to rival systems they remark that, notwithstanding all that has been stated and published in recent times respecting the continuous-wave system of wireless telegraphy, experience has not yet proved that that system will be capable of conducting a long-distance wireless telegraph service as efficiently as the slightly damped spark system at present in use.

The report of the Select Committee appointed by the House of Commons in April, 1912, to inquire into the wages and conditions of employment in the Post Office has issued its report. It finds that, with the exception of a few of the more highly skilled branches of the engineering department during periods of abnormal expansion of work, there is no difficulty in obtaining a sufficient number of competent persons. With reference to wireless, the Committee recommends that the staff be recruited by selection from telegraphists, counter and sorting clerks between twenty-one and twenty-four years of age, and showing proof of such knowledge of French and German as is necessary for communicating with foreign ships. It recommends 70s. as the maximum weekly wages for this class; and thinks that the salaries of wireless overseers should be £200, rising to £230 a year. The Committee also states that no clear case that the undertakings of the Postmaster-General with regard to the transfer of the staff of the National Telephone Co. have not been carried out has been sustained. The staff therefore has no ground of complaint, and will share, says the report, in the advantage of the recommendations made in regard to the whole body of Post Office servants.

Private wireless stations in Germany may now only be erected on the understanding that any messages picked up are kept secret, and that the Government has the right at any time to order their demolition. Military and naval officers can at any time inspect the stations and order a temporary cessation of activity, and the stations must be placed at the disposal of the Government when required.

At the fortnightly meeting of the Liverpool Amateur Wireless Association, last Thursday, one of the members gave particulars of his station, from which vessels are heard all round the coast of England, as well as from some parts of the coasts of Ireland and Scotland. Many of the Continental stations are strongly received, including Bergen, Norddeich long and short wave, Belgium, France, and Spain. Soller (Balearic Isles) and Pola (Austria) are very often easily readable. A double slide inductance coil is used, with an extra coil of inductance for Clifden. The sliders on this set make contact with at most two turns of inductance. Very sharp tuning is obtained. Prof. Marchant has promised

to give a lecture on wireless in the near future, and the members are looking forward to a visit to the wireless installation at the Liverpool University. The next meeting was announced for Thursday, 28th August.

The first of a series of schools of wireless telegraphy is to be erected at Giffnock for the Faraday Correspondence Schools, Ltd. (Glasgow). There will be six portable wireless sets for transmitting up to twenty miles and receiving up to 150 miles. A very powerful station with an aerial supported on masts from 150 to 200 ft. high and about 250 ft. apart is also to be erected. Accommodation for about 150 students at any one time is to be provided.

The Roumanian Office states that new telegraph stations at Dobritch and Baltchik have been opened, known as Dobryci and Balcie.—As from the 14th inst., telegrams in code and cipher were again admitted by Greece.—A telegraph office has been opened at Durazzo (Albania) under the same conditions as Vallona.

## ELECTRIC TRACTION NOTES

### The Motor-'Bus Danger: Traffic Committee's Report

IF the Government give effect next session to the recommendations of the Select Committee on Motor Traffic (whose report was issued on Thursday evening), the London County Council and the suburban Local Authorities owning tramway undertakings will have reason to rejoice. The London Borough Councils, on the other hand, may be less pleased, and the owners of motor-'buses will not be pleased at all. The chief recommendation is that the licensing of stage carriages and hackney carriages should be transferred from the police to the County Councils and County Borough Councils, who shall also have power to issue regulations as to routes, time-tables, &c. These powers, it is suggested, are to be subject to a sort of general control by the Traffic Branch of the Board of Trade, which is to be reorganised for the purpose. The veto of Borough Councils with regard to tramway schemes is to be taken away, and in the case of opposition a hearing before this new Traffic Branch is to be substituted.

Needless to say, this would help considerably to mitigate the serious effect which motor-'bus competition has had upon the tramway undertakings, but, however desirable the recommendations of a Select Committee may be, and however well considered its report, it by no means follows that immediate legislation will follow. As the Committee points out, the whole problem of London traffic was inquired into by a Royal Commission in 1903-4-5; but, although made eight years ago, most of the recommendations of this Commission "have only become more urgent with the time which has elapsed since they were made."

A very exhaustive analysis of the street accidents in London during the past few years has shown an enormous increase year by year, and the Committee has satisfied itself that by far the greater part of the responsibility for this increase must be attributed directly to the motor-'bus. In addition, the methods employed by many 'bus drivers when running competitively with tramways are, in the opinion of the Committee, serious from the standpoint of public safety. Tramways, on the other hand, are held to be entirely free from blame for the increase in street accidents. Fatal accidents have been as frequent in streets in which there are no trams as in streets with tramlines, and the Committee "do not think that anything has been shown to connect with tramways, even indirectly, the alarming rise of fatalities in recent years." The suggestion that the licensing authority for motor-omnibuses should, in London itself, be the largest tramway authority, and in suburban London the County Councils, who will naturally be usually inclined to adopt the views of the local authorities running the trams, is somewhat drastic, but it appears to be almost justified; and, even if these authorities may be tempted to restrict omnibus traffic facilities unduly, the omnibus owners would always have an appeal to the traffic branch of the Board of Trade already mentioned.

Incidentally, it may be mentioned that the Committee find that lack of lighting has not been a contributory cause of the accidents. Taken over a period of three years, statistics showed 508 fatalities before sunset as against 355 after, and of the latter, 339 occurred where lighting was good, four in places not lighted and twelve with lighting medium or indifferent. Those tramway authorities who have found road-

widenings a burden, may or may not be comforted to hear that narrowness of the street does not conduce to a greater number of accidents; motor-omnibuses run more frequently in the wider streets. Nor is there anything to show that accidents would have been sensibly diminished if a speed limit had been enforced.

In fact, the tramways are blamed for nothing; practically the only recommendation for their improvement is that means should be taken as soon as possible to remove the congestion caused by "dead ends."

A system of stopping moving trains by wireless has been invented by Professor C. Wirth, of Nuremberg, who was also the inventor of the "wireless distance boat." The system has been inspected by Dr. Otto Edelmann (Chief Engineer, Bavarian Royal Institute of Industry and Commerce) in operation on the line between Nuremberg and Gräfenburg, in Bavaria. The telephone or telegraph lines alongside the railway are used as sending antennæ, while wires on the roof of the train serve as receiving antennæ. Sending stations are required every 80-100 kilometres, and are connected to intervening stations and signal boxes, where sending apparatus, either hand or automatic, is installed. A signal received on the train may be used to give a warning, apply the brake, shut off steam, &c. The cost of installation is said to be very low. Messrs. H. J. C. Grave & Co. (27-28 Old Jewry, E.C.) are representing the inventor in the United Kingdom as well as in other countries.

When the Report stage of the Post Office (Tube) Railway Bill was continued on Thursday last, an amended clause relating to the supply of electrical energy for the railway was proposed by the Government instead of the one originally in the Bill and deleted by the House of Lords Select Committee, as announced in ELECTRICAL ENGINEERING last week. The clause provided that the Postmaster-General should invite tenders for the electricity supply, and that if he were satisfied, taking all the circumstances into account, that an appreciable saving would result from taking the supply from a company or local authority, he should adopt that course. The Earl of Donoughmore suggested that the words "taking all the circumstances into account" should be omitted. The clause, subject to this amendment, was then agreed to, and the Bill read a third time and passed.

The trolley-omnibus system at Ramsbottom was opened for traction last Thursday. The route is five miles in length, and power is supplied by the Lancashire Electric Power Co. The cars have been supplied by the Railless Electric Traction Co.—A railless scheme is also being considered for Reading, and the Council has decided to promote a Bill for the purpose in the next session of Parliament.

A dividend at the rate of 5 per cent. per annum has been declared on the ordinary shares of the Oldham, Ashton & Hyde Electric Tramway Co.

A report has been prepared on the working of the Dublin & Blessington Light Railway, which is at present run by steam. It is stated that the cost per train mile is no less than 19'6d., and this is compared with a similar cost of 3'9d. for the electrically worked Lucan tramway as an argument in favour of the conversion of the line to electric traction.

Several sections of the new electric tramways in Constantinople are now complete, and were opened for traffic last Saturday.

A loss of £2,865 has been made on the year's working of the Walthamstow tramways, compared with last year's profit of £1,800. The change is attributed to motor-omnibus competition.

## LOCAL NOTES

**Bath: Electricity Accounts.**—A total expenditure of £11,846 is recorded for the past year, of which £7,332 is for generation and purchase of current, and £1,118 for distribution. The receipts were £22,130, but the balance was insufficient to pay capital charges, &c., and a deficit of £1,445 is the final result. Last year's deficit was £1,521, which has been met from the rates.

**Foleshill: Electricity Supply.**—The Midland Electric Light and Power Co. has given notice of its intention to apply to the Board of Trade for a provisional order in this district.

**Gravesend: Electricity Accounts.**—The profit on the year's working of the electricity undertaking was £166, out of which £120 has been applied to the wiring of the Technical School;

£25 was carried to capital account, and the remainder carried forward.

**Louth: Electricity Supply.**—It is reported that a London firm of electrical engineers has intimated its intention to apply for a provisional order for a supply of electricity in this district.

**Macclesfield: Mains.**—The New Electricity Co. are being asked by the Water Committee of the Corporation to give an undertaking to lay their cables in a trough insulation surrounded by 6 in. concrete for at least one yard each side of the water main in every case where the cables are laid under or over such mains.

**New Brighton: Interruption of Supply.**—On Saturday night, at about 9 o'clock, owing to failure of a feeder cable, supply was interrupted and considerable inconvenience caused. The Electricity Department were, however, able to effect the necessary repairs in about an hour.

**Portsmouth: Electricity Supply.**—A Committee has been appointed to consider the advisability of providing a supply of electricity for this district.

**Sheffield: Wiring Department.**—The report of the Electricity Committee regarding the future working of the Installation and Motor Department is to be referred to a Special Committee for further consideration in view of the opposition by local contractors regarding the scheme for the supply of fittings.

**Swanage: New Generating Station.**—The Board of Trade has given their consent to the construction of a generating station by the Swanage Electricity Supply Co. on a certain site.

**West Bromwich: Electricity Accounts.**—A net profit of £337 has been made on last year's working, after payment of capital charges, &c.

**Witney: Charges for Power.**—The following new scale of charges for power supply has been adopted:—Under 300 units per quarter, 2½d. per unit; up to 700 units, 2d. per unit; and exceeding 700 units, 1½d. per unit.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

### Generating Stations, Sub-Stations, Mains, &c.

**Basingstoke.**—Tenders are shortly to be invited for Diesel engines, generators, balancers, storage batteries, switchgear, cables, and overhead travelling crane.

**Batley.**—A Local Government Board inquiry is to be held regarding a proposed loan of £8,206 for mains, arc lighting, meters and services, and £1,550 for a new feeder cable.

**Belfast.**—A Local Government Board inquiry will be held on September 9th into the application for a loan of £35,000 for electrical purposes.

**Bingley.**—A Local Government Board inquiry is to be held regarding a loan of £7,000 for the electricity undertaking.

**Burton-on-Trent.**—New switchgear and new cables are to be put in at a sub-station at a cost of about £120.

**Cardiff.**—A Local Government Board inquiry is to be held next Tuesday regarding a loan of £30,500 for the electricity undertaking.

**Edinburgh.**—Tenders are invited by September 22nd for two 1,500-kw. mixed pressure steam turbines and D.C. generating plant at Edinburgh. Particulars from Sir A. W. B. Kennedy, 17 Victoria Street, S.W. (See advertisement on another page.)

**Heywood.**—An application for the expenditure of £12,000 is to be made for transformer plant, cables, &c., to deal with the bulk supply from the Bury Corporation.

**London: L.C.C.**—Tenders are invited, by September 23rd, for additional main high-tension switchgear and reconstruction of existing switchgear at the Greenwich Generating Station. (See advertisement on another page.)

**Newport.**—A Local Government Board inquiry is to be held regarding a loan of £10,600 for the electricity undertaking.

**Plymouth.**—Tenders are invited for a steam turbo-alternator and condenser. Particulars from E. G. Okell, Borough Electrical Engineer. Tenders by August 27th.

**Tunbridge Wells.**—Tenders are invited for the supply of high and low-tension cables for the ensuing twelve months. (See advertisement on another page.)

**Wimbledon.**—Tenders are invited for the supply of a 1,500-kw. alternator with condensing plant, and 20-ton over-

head travelling cranes. Particulars from Mr. H. Tomlinson Lee, Borough Electrical Engineer. Tenders by Sept. 1st.

### Wiring

*The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.*

**Abbey Wood.**—Extensions to tramcar depôt.

**Canterbury.**—New buildings to Bury Asylum. Architects, Jennings & Gray.

**Cardiff.**—New fire station.

**Grimsby.**—New isolation hospital.

**Haslingden.**—Conversion of buildings into wards at the Union. Architect, Henry Ross, 15 Cannon Street, Accrington.

**Hyde.**—Tenders are invited for electric lighting fittings, ventilating fans, &c., at the extensions of public baths. Particulars from H. J. Fletcher, 45 Clarendon Place.

**Ipswich.**—Additions to infirmary. Surveyor, Northgate Street.

**Keighley.**—Tenders are invited for wiring of a Sunday School in Albert Street. Architect, Mr. A. P. Harrison, High Close.

**London.**—Home Office Museum, Horseferry Road, S.E. H.M. Office of Works.

**Manchester.**—New brewery for Arthur Guinness, Son & Co.

**Morley.**—Cinematograph theatre. W. Peel, Schofield Park Road, Leeds.

**Northumberland.**—Tenders are invited for an electric lighting installation at Trimdon Colliery.

**Sunderland.**—Cinematograph theatre. W. & F. R. Milburn, Architects.

**Warrington.**—New imbecile block and offices at the work-house. W. & S. Owen, Cairo Street.

### Miscellaneous

**Aberdare.**—The Powell Duffryn Steam Coal Co. invite tenders for a supply of electrical goods. Particulars from Stores Manager, Aberaman Offices, nr. Aberdare.

**Tilbury.**—The Port of London Authority invite tenders for twelve electric luffing cranes, similar to those recently ordered for the Albert Docks.

## MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. George Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £72 15s. to £73 5s. (Last week, £72 10s. to £73.)

**The Record Patent Battery Auto Cut-In and Cut-Out.**—Owing to a printer's error, the price of the Record Electrical Co.'s Battery Auto Cut-In and Cut-Out advertised in our last issue was given as from £5 subject, instead of from £3 subject.

**Australian Trade.**—W. G. Watson & Co., Ltd. (Sydney), who have opened an office at 41 Cheapside, E.C., with the object of buying electrical goods for the Australian market, will be glad to see any of the trade or manufacturers who wish to do Australian business before the 30th inst.

**Self-Contained Locomotives.**—We understand that the sole selling licence in the Australian Commonwealth for Paragon self-contained locomotives, in which an electrical transmission system (W. P. Durnall's Patents) is employed, has been purchased by Messrs. Elder, Smith & Co., Ltd., of Adelaide and London. A manufacturing licence for locomotives and rail-cars on the "Paragon" system has been granted to Messrs. R. & W. Hawthorne Leslie & Co., Ltd. (Newcastle-on-Tyne).

## THE RECORD ELECTRICAL Co., Ltd.

LONDON OFFICE:  
CAXTON HOUSE,  
WESTMINSTER, S.W.

Telephone:  
3057 Victoria.  
Telegrams & Cablegrams:  
"Infusion,  
London."

MEASURING  
INSTRUMENTS.

RECORD'S PATENT.

Write for Prices & Particulars.

WORKS:  
BROADHEATH,  
MANCHESTER.

Telephone:  
164 Altrincham.

Telegrams & Cablegrams:  
"Infusion,  
Altrincham."

**Change of Title.**—The title of the firm Kelvin & James White, Ltd., has been changed to Kelvin, Bottomley & Baird, Ltd., in order to avoid possible confusion with the name of another firm of nautical instrument makers.

**Works Sports.**—The employees of A. Reyrolle & Co. held their annual sports at Hebburn on Saturday last, followed by a dinner and a dance.

**W. T. Henley's Telegraph Works Co.**—An interim dividend on the preference shares at the rate of 4½ per cent., and on the ordinary shares at the rate of 10 per cent., has been declared.

## NEW COMPANIES

**IGRANIC ELECTRIC CO.**, 147 Queen Victoria Street, E.C. Capital £35,000. To carry on the business relating to electrical control gear, &c., of the Adams Manufacturing Co. First directors, F. R. Bacon, F. L. Pierce, A. W. Berresford, and G. A. Mower.

**MITCHELITE LIGHTING CO.**, 161 Piccadilly, W. Capital £25,000. To adopt an agreement with C. H. Purvis. First directors, T. D. Stubbs, B. B. Sanders, A. W. Heron-Maxwell, C. H. Purvis, S. L. Elphinstone-Ollif, and J. W. Purvis.

**REINEKE'S WIRELESS TELEPHONES, LTD.**, Norfolk House, Norfolk Street, W.C. Capital £25,000. (Private company.) To adopt an agreement with J. F. Reineke and others regarding inventions relating to wireless telephony for mines, &c. First directors, Sir Archer Croft, L. W. Holmes, G. MacElwee, E. D. Young, G. S. Goldie.

## APPOINTMENTS AND PERSONAL NOTES

Mr. Robert Hammond is, we understand, starting for South Africa on the 30th inst., by the R.M.S. *Edinburgh Castle*.

Mr. F. W. D. Stubbs has been appointed Canvassing Engineer at Sheffield at a salary of £130 per annum, and Mr. S. C. Hurry as Chief Canvasser in the Publicity Department at the same salary, with Mr. H. E. Betts as Additional Canvasser at £117 per annum.

A young man with practical experience in telegraph and telephone repairs is wanted in the West Indies. (See advertisement on another page.)

**The Joint Meeting of the British and French Institutions of Electrical Engineers.**—An extra number of the *Bulletin* of the Société Internationale des Electriciens has just been issued, containing a verbatim report of the Proceedings at the joint meeting of the British and French Institutions in Paris last May. The Papers on electric railways, however, are published only in abstract, as they had appeared in full in previous issues of the *Bulletin*. The long Paper by M. Maurice Leblanc, giving a *résumé* of the present position of electric power transmission at very high pressures, is given in full. A special number of the *Journal* of the Institution of Electrical Engineers is also in preparation, containing all the Papers read (including translations of the French Papers), and a report of the discussion in English.

**Wireless Wonders!**—It was reported in the *Standard* last week that Signor Ulivi has demonstrated outside Havre a method of exploding at distances varying from 600 yds. to 12 miles charges hermetically sealed in metal receptacles and sunk in the ocean. Among those present at the tests may be mentioned Major Ferrié, Chief of the Wireless Company of the Eiffel Tower, and other officials of the French Government, so that the scheme is evidently regarded as containing great possibilities, but doubts are expressed by correspondents in the French Press as to the genuineness of the experiments. It is stated that other vibrations having frequencies of the order of those used in wireless telegraphy are by some means focussed on to the vessel, which is at least partly of metal, containing the charge to be exploded. We gather that at a certain critical value these waves are supposed to cause ignition of the charge by vibration or by some electric action due to resonance. It is said that the "radio-magnetic" capacity of the metal receptacle has to be determined before the explosion can take place with certainty.

## SUMMARY

THERE is a strike of wiremen employed by contractors working for H.M. Office of Works. The matter has been considerably exaggerated in the daily press, and a correct statement appears on p. 486.

AN article by Mr. John B. Sparks deals with the supply of current to single-phase railways. The various methods of feeding single-phase railways from three-phase supply systems of different pressure or frequency are described, and the alternative of single-phase generation is discussed. (Page 486.)

THE first half-watt per c.p. tungsten lamps to be shown publicly in this country were exhibited to Press representatives by the British Thomson-Houston Co. yesterday afternoon. (Page 487.)

THE power gas and by-product recovery plant at the Accrington electricity works has now been satisfactorily working for some time. The plant consists of two "National" gas engines of 1,000 b.h.p. direct-coupled to 6,600-volt three-phase 50-cycle Peebles alternators running at 200 r.p.m. The gas is generated in a producer plant, and about 10 tons of tar and between 3½ and 4 tons of ammonium sulphate are recovered from the local bituminous coal used. It is found that the consumption is about 1½ lb. of coal per unit generated at the present load factor. (Page 488.)

A NEW line of rotary snap switches is described and illustrated. (Page 490.)

THE merits of A.-C. and D.-C. driving in a particular

factory are discussed in our Questions and Answers columns. (Page 491.)

A BRIGHT-GLOWING, easily replaceable heating element is illustrated and described. (Page 491.)

THE lowering gear for the metal filament lamp lighting in Fulham is illustrated. (Page 492.)

SINCE 1903 the number of trunk telephone lines has increased from 1,363 to 3,180. The operating cost per call has remained practically stationary at 1.26d.—Owing to a dispute with the Douglas Town Council (I.O.M.) as to the payment for wayleaves, the Postmaster-General has notified a number of subscribers that their instruments will be disconnected.—The Marconi Co. claims to be ahead of its rivals in wireless telephony.—Rules relating to the reception of wireless time signals in Germany have been issued. (Page 493.)

THE Greenock Corporation intends to acquire the undertaking of the Greenock and Port Glasgow Tramways Co.—An agreement has at last been come to between the Llandudno and Colwyn Bay Electric Railways Co. and the Colwyn Bay Council as to the extension of the Company's lines into Old Colwyn.—A proposal to convert the horse tramways in Stirling to electric traction, under certain conditions, is afoot.—A partial strike of tramway motor-men and conductors is in progress in Dublin. (Page 493.)

SPECIFICATIONS published by the Patent Office on Thursday last included patents for maintaining a uniform temperature in freight vans, a variable-speed dynamo with the field windings in sections and the necessary switchgear for connecting in series or parallel, and some details for lock and block railway signalling.—A patent for snap switches expires to-day after a full life. (Page 494.)

THERE has been arbitration at Bromley (Kent) in connection with the laying of mains for bulk supply.—Some discussion has taken place between the Stirling electrical contractors and the Corporation on the question of the sale of fittings.—The Glasgow Corporation is installing two 6,000 kw. sets at the existing power stations, pending the erection of the new generating station.—A bonus scheme suggested by the Dewsbury Borough Electrical Engineer has been rejected by the Electricity Committee in favour of an increase of wages to the workmen. (Page 495.)

A CONSULTING engineer has been appointed at Waterford; high- and low-tension mains and switchgear are required at Hammersmith; portable electric winches at Aberdeen; steam boilers at Southampton; and electrically-driven plant at Penwortham.—An underground electric railway is to be constructed in Brazil; meters and maximum demand indicators are required by the Melbourne Corporation; and electrical machinery for operating pneumatic tube by the Melbourne Postmaster-General. (Page 496.)

A COMPANY has been formed to acquire from Marconi's Wireless Telegraph Co. the patent rights of the Betulander automatic telephone. (Page 496.)

## WIREMEN'S STRIKE IN LONDON

THERE has been a small strike of engineering fitters and labourers (including some electrical wiremen) employed on maintenance contract work for His Majesty's Office of Works, chiefly at the Admiralty Building. No serious stoppage of work has been occasioned or is likely to be occasioned by it, and the daily newspaper reports have considerably exaggerated the matter; the only effect has been the cessation of certain general overhauling, repair, and small extension wiring work which was in progress at some of the Government buildings.

Through the courtesy of His Majesty's Office of Works, we are able to give the exact facts of the case.

About the beginning of July, the engineering labourers employed by one of the contractors to the Office of Works (Messrs. James Simpson & Co., of Pimlico) applied for an increase of pay from 7d. to 7½d. per hour, on the ground that they are builders' labourers, and that the terms of a recent settlement for the higher rate of wages should apply to them. The First Commissioner of Public Works was only concerned as to the application of the Fair Wages Resolution of the House of Commons, and explained that, for him to order the increase in wages, it would be necessary that he should have it proved to him that the 7½d. rate was paid to engineering labourers in the district. Twenty-one firms were cited by the men's representatives as paying this rate, but on enquiry it was found that only three, or at most four, firms paid it. In the circumstances, it was not possible to recognise this as the rate prevailing in the district, so that the Commissioner did not see his way to interfere, but on Monday last he offered to refer the matter to the Board of Trade for arbitration.

Meantime, a painter's strike occurred last Monday; all the Union painters went out, but three non-union men remained at work. The London District Secretary of the Electrical Trades Union called out the electrical wiremen (employed by the contractors for the electrical maintenance work, Messrs. Wilson & Smith) "in sympathy," and with these higher grade men out, the labourers were also thrown out of work. To what extent the electricians on strike are supported by the Electrical Trades Union headquarters at Manchester is not known. Inquiries which we have made from several of the leading wiring contractors in London have elicited the information that very few Union men are included among their workmen—in fact, several of the larger firms employ no Union men at all. There is therefore very little danger of the wiremen's strike spreading generally—unless the threatened general strike in the building trades takes place.

Among the statements circulated by the daily Press which are incorrect, is one that the fountains in Trafalgar Square were stopped owing to the men in charge of the pumps coming out on strike. The fountains were stopped until yesterday, it is true, but this was simply owing to a breakdown in one of the pumps.

Another statement, to the effect that the lifts at the General Post Office might be stopped, is equally wrong. The Post Office works the lifts with their own men, and the Office of Works merely looks after the repair of the lifts.

None of the Post Office or Admiralty workmen are on strike.

In the Engineering Department of the Post Office, at which we have also made inquiries, the chance of any action by the staff which would endanger the supply of electrical energy from the Blackfriars Power Station or interfere in any way with the Post Office business as far as the Engineering Department is concerned with this, is looked upon as an impossibility. In this connection, perhaps, attention may be drawn to the discussion which took place before the House of Lords Committee a week or two ago, when the Post Office Tube Railway Bill was under consideration. Counsel for the London electric supply companies was endeavouring to foretell the effects of a strike by the employees at the Blackfriars Power Station, with a view to showing that dependence for a supply of electrical energy should be placed upon the various London companies instead of upon one source of supply. Mr. W. Slingo, Engineer-in-Chief to the Post Office, admitted that in the past, Post Office employees had threatened to strike, but, speaking with an inside knowledge of what was taking place on the last occasion when a strike was threatened, he said he knew that there was never the slightest possibility of the threat being put into effect, and he followed this up by the statement that so long as he was at the Post Office he would undertake that there would not be a strike in the Engineering Department.

## THE SUPPLY OF CURRENT TO SINGLE-PHASE RAILWAYS

By John B. Sparks

IN discussing the merits of single-phase traction, so much attention is given to the manner and efficiency with which the current is to be utilised that the methods by which it is to be generated and supplied to the overhead line are sometimes barely considered. As the overhead construction and the train equipment become more standardised, however, it will be found that the method of supplying current to the line will become a problem of equal importance, and it may even become the determining factor as to the system which will be adopted.

The railway could have its own station generating single-phase current at the required pressure and frequency; but a cheap local supply may be available, and in such event the purchase of power would appear to be the logical and most economical solution, especially if the railway be a small one. Now, with but few exceptions, all the large power-supply undertakings, both in Europe and in America, generate and distribute three-phase, a form of power not directly applicable for feeding a single-phase railway. Besides the difference in form, there may also be differences of frequency and pressure. The last-named is of little account, in consequence of the simplicity and high efficiency of the static transformer, but the other two offer serious difficulties.

Taking, first, the case where the frequency of the single-phase railway is the same as that of the available three-phase supply, there are at least four methods of supply to select from.

First, the railway network may be divided into three or more separate sections insulated from one another, and the overhead contact conductors and feeders of the several sections may be fed separately from one or other of the three phases of the three-phase supply. In this case the track rails (and any return cables in parallel with them) of all the three or more sections are connected together, and form a common neutral. If equal traffic is running over each of the three sections, as should be arranged for, the track currents balance out. If, however, the loading is unequal, a resultant current flows back to the generator neutrals, to which the track rails are connected. Any unbalancing produces, of course, a variation of pressure, which may be great enough to affect seriously the lamps and small motors connected to the system. Besides this disadvantage, there is the difficulty of insulating the sections from each other, and the possibility of a short circuit when a train passes from one section to another, as the two sections have the full delta pressure between them.

These difficulties are not insurmountable, however, and the above was actually the system advocated by Mr. C. H. Merz for the Melbourne suburban railways in the event of single-phase traction being adopted. In this case no pressure transformation was required either, as the delta pressure of the three-phase supply was to be 20,000 volts, giving the required phase pressure of 11,000 volts for the single-phase railway system. The absence of transformers between the railway system and the power network might have proved to be a disadvantage, however, as they protect the network most effectively from the heavy surges frequent in single-phase railway systems. The frequency at Melbourne was to be 25 cycles per sec., a frequency adapted both to the single-phase railway and to the general power supply from the three-phase mains.

The second method is to transform the three-phase supply to two-phase by means of the well-known Scott transformer connection (in which one primary terminal of a single-phase transformer is connected to the middle point of the primary of a second transformer—the remaining three terminals are connected to the three-phase supply, and the secondaries give two-phase currents.) There are then only two phases to consider, and the railway network may be divided into two separate systems insulated from one another, as above; or, if the rush-hour traffic is in both directions, the "up" and "down" lines may be fed respectively from the two phases. If the difficulties at crossings can be overcome by suitable insulated sections between the conductors of the two phases, and the short-circuiting of the two phases by trains passing from one phase to the other prevented, this is the better solution, as the loading of the two phases is more likely to be equal. As in the three-phase case, the rails of both "up" and "down" lines form a common neutral. This system has been applied in the case of the 25-cycle, single-phase line between Rotterdam, Scheveningen, and the Hague, but with what result the writer is not aware. (A similar difference of pressure between the "up" and "down" contact wires

exists on the extension of the New York, New Haven & Hartford railway, where a three-wire, single-phase system is in use, the track forming the neutral.)

The third plan is only applicable in the case of a three-phase system with an unearthed neutral, and consists in connecting not the neutral, but one phase to the track rails, and the overhead line to one or other of the other phases. The single-phase railway is thus supplied at the delta pressure, and two phases only of the generator carry the railway current. This method is the one adopted by the London Electric Supply Corporation for the supply of the London, Brighton & South Coast Railway's electrified lines, and it is said that it was found possible to connect a small three-phase power load to the same generators. The pressure fluctuations would be troublesome, however, and it has probably been found advisable to keep the railway and power loads on separate machines in this instance.

The generators in single-phase generating stations are commonly three-phase machines used in this manner; the third phase forms a spare winding, or it may be left unwound.

The fourth system (with equal frequency) is to instal substations with motor-generators consisting of synchronous three-phase motors, direct-coupled to synchronous single-phase generators. The latter may generate at the contact-line pressure, but generally it will be found advantageous to transform up, partly on account of the greater reliability of low-pressure generators, but chiefly on account of the protective action of the transformers, already mentioned. The use of motor-generators, however, reduces very considerably the overall efficiency of the supply. On account of the complete conversion and the comparatively low efficiency of the single-phase generator, the overall efficiency of such a motor-generator substation, even under the best conditions of load factor, would not be more than 75 per cent., as compared with an efficiency of 85 per cent. obtained with three-phase to direct-current rotary-converter substations. One of the chief advantages of the single-phase system is therefore eliminated by this method.

Where the frequency adopted for the railway system is different from that of the supply, however, such motor-generators, or frequency-changers as they are then called, must perforce be employed if current is to be taken from the general supply system. Several continental railways are supplied in this way. Thus, the Bevers-Zuoz-Schuls and the St. Moritz-Pontresina sections of the Rhaetian Co.'s Engadine system are fed with single-phase current at 10,000 volts, 16 $\frac{2}{3}$  cycles from motor-generator substations supplied with three-phase current at 25,000 volts 50 cycles from the famous Brusio water-power station, which already supplies (through three-phase-D.C. motor-generator substations) the Bernina railway from St. Moritz to Torino. The motors of the motor-generator sets have, of course, three times the number of poles that the single-phase generators have, so as to obtain the desired ratio of frequency.

Another example is the Rjukan single-phase railway, described in *ELECTRICAL ENGINEERING*, July 31st, 1913, p. 441. This case is identical with the above.

A further example is the Wiesenthal line of the Baden State railways. Power for this is obtained from a local company supplying at 7,000 volts, three-phase, 50 cycles, while the railway is 15,000 volts, 16 $\frac{2}{3}$  cycles, single-phase. The energy is purchased at a fixed sum per annum up to a maximum demand of 1,040 kw., with an increased rate for the units taken over this limit. To keep down the peak, direct-current battery storage has been adopted, as described in detail in *ELECTRICAL ENGINEERING*, June 28th, 1913, p. 385. The substation at Basle contains two three-phase-single-phase motor-generators, each with a D.C. machine direct-coupled. These latter are connected with a battery of 2,200 amp.-hour capacity, and act as motors or generators, according to the railway demand, either helping to drive the single-phase alternators or charging the battery. The single-phase alternators generate at 15,000 volts, 16 $\frac{2}{3}$  cycles.

It may be noted that a similar attempt to reduce the peak load is also being made in the case of the Bardonnecchia substation of the Turin-Modane three-phase railway. This is a 25-cycle line, and the available supply is 50 cycles. Motor-generator sets or frequency changes will be used, and it was proposed to provide each set with a heavy flywheel and a special machine to reduce the speed on peak loads, and thus make use of the stored-up energy of the flywheel, and reduce the maximum demand on the generating station.

As mentioned above, where it is necessary to employ motor-generator conversion, a serious drop in the overall efficiency of supply is effected. The only alternative, when the frequency of supply is not that of the railway, is for the

railway to have its own generating plant, and a number of the large single-phase railways, therefore, have their own power stations. The economic disadvantages of this solution cannot, however, be over-estimated. Apart from the greater size and cost per kw. of single-phase generators, as compared with three-phase machines, both the railway and the community as a whole are prevented from benefiting by the improved load factor of the station with a combined power, lighting, and railway load. This important consideration was strongly emphasised in a Paper by Mr. Samuel Insull, President of the Edison Commonwealth Co., Chicago, read before the American Institute of Electrical Engineers last year. Mr. Insull points out that, owing to the diversity of load between railway and power-supply, a very great improvement in load factor is effected by a combination of these supplies, and he mentions the case of the New York, New Haven & Hartford single-phase station, with a load factor of about 25 per cent. only, and compares this with the 60 per cent. load factor of a combined station. The load factor of the Chicago station, with a comparatively small railway load only is over 48 per cent. (See *ELECTRICAL ENGINEERING*, July 10th, 1913, p. 403.)

It is possible, however, for the railway to have its own generating plant allotted to it, housed in the same station as the power and general supply plant, and supplied from the same boilers, so that the gain in the load factor of the whole station is not lost. If the difficulties of the three-phase-single-phase conversion are such that separate generating plant is deemed advisable, this should usually be the best solution, unless three-phase current can be bought at so low a rate that the additional cost of conversion does not matter.

## THE HALF-WATT LAMP

THE first public exhibition of the half-watt per c.p. tungsten lamp in this country was given at Mazda House yesterday afternoon by the British Thomson-Houston Co., Ltd., to members of the electrical Press. Mr. F. W. Willcox explained on behalf of the company that the credit of evolving this lamp belonged to the B.T.-H. and associated companies, having been developed first at the laboratory of the Schenectady works by Mr. W. C. Whitney. The lamp was, he said, being further developed at Rugby, and the specimens shown had been made there. The lamps exhibited, which were burning at their rated wattages, were as follows: a 1,400 British c.p. lamp, at 0.52 watt per British c.p.; a 1,375 c.p. lamp at 0.53 watt per c.p.; a 1,260-watt lamp at 0.535 watt per c.p., and a 1,600-watt lamp at 0.50 watt per c.p. All were supplied at about 80 volts.

The lamp has passed the experimental stage, and it is hoped that some sizes will be on the market well before the end of the year. The first ones that will be obtainable will probably be 300 c.p. 150-watt lamps at from 60 to 80 or 100 volts, with a useful life of 1,000 hours, and sizes up to 1,500 c.p. and over will follow.

The filament, we understand, is of pure tungsten, and the globe is filled with an inert gas.

We hope to publish further particulars in our next issue.

**Finsbury O.S.A. Magazine.**—The August issue of the Finsbury Technical College Old Students' Association Magazine contains a short biography and a portrait of Mr. H. A. Humphrey (the inventor of the Humphrey pump), who is the President of the Association. Besides official and editorial notes there are reports of various recent social functions connected with the Association, a description of a visit to Dover Harbour works, some remarks on engineering in Paraguay, notes on old students' doings, and a list of officers for the current session.

**A Long Delayed Controller Patent in the U.S.**—We learn from the *Electrical World* (New York) that an unusually broad and comprehensive patent for an electric controller was granted to Mr. H. Ward Leonard by the United States Patent Office on June 17th last. The application was lodged on December 12th, 1904, nearly nine years ago. The patent covers the use of a system of electromagnetic contactors for automatically cutting out motor starting resistances, and also means for utilising the same contactors and resistances in automatic electrodynamic braking. It is applied to the multiple unit control of trains. There are 64 claims.

# PRODUCER GAS PLANT AT ACCRINGTON ELECTRICITY WORKS

## Complete By-Products Recovery Plant

THE first municipal producer gas and by-product recovery plant to be put to work, in this country at least, is to be found at Accrington, where the Borough Electrical Engineer, Mr. H. Gray, has installed two complete 1,000-h.p. generating sets on this principle. The steam plant in the station has been retained, and is used for the peak loads. This plant generates at 460 volts direct current, while the two new 1,000-h.p. sets are accommodated in the original building, and generate at 6,600 volts, three-phase, 50 cycles. There is ample space for extensions. The producer plant is erected on the ground at the back of the generating station, and there is also a water reservoir at a higher level than the generating station, and additional buildings containing a chemical laboratory for effecting tests of the by-products, of the producer gas, and the fuel used, &c.

The gas engines are each rated at 1,000 b.h.p. (200 r.p.m.), and were supplied by the National Gas Engine Co., Ltd. (Ashton-under-Lyne), and our representative who visited the works was informed that during the time they have been working some important improvements have been carried out. They were originally arranged with pipe lubrication, but by fitting new hollow connecting rods and rearranging the oiling system, the oil consumption has been reduced by 50 per cent., as it is not burnt up on the cylinder walls to such an extent as formerly. Each engine is fitted with duplicate ignition circuits supplied from low-tension Bosch magnetos. There are thus two independent sparking plugs to each cylinder. The eight cylinders are arranged vertically in four tandem pairs, the diameters being 22 in. and 23 in. for the lower and upper rows, so that the upper pistons may be withdrawn easily. Direct-coupled to each engine is a 938 k.v.a., 6,600-volt, three-phase, 50-cycle alternator, supplied by Bruce Peebles, Ltd. (Edinburgh). The chief alteration from standard for this class of alternator is in the fact that the windings are specially treated and have large creeping surfaces, in case gas or fumes should be encountered, though their presence has not yet been detected in the engine room. The stators weigh 21 tons, and of course a heavy flywheel has been provided for each set. Each set drives a 12-kw. exciter. Two 200-kw. and one 425-kw. motor-generator sets, converting from 6,600 volts three-phase A.C. to 460 volts D.C., have been put in, and they can be used in either direction, though they are used to give a supply to the 460-volt network from the new A.C. generating sets. They are arranged for three-wire balancing on the D.C. side. They were supplied by the General Electric Co., Ltd. (Witton).

Before passing to a description of the producer and recovery plant, it is well to indicate how the engines and their immediate auxiliaries operate. The producer gas for the engines requires the presence of air for its complete combustion in the cylinders, and this is sucked in through specially designed "admitters" in the suction pipe, which are very silent in action. After combustion in the cylinders the exhaust gases are led through a special locomotive-type boiler in the boiler house, where steam at approximately 100 lb. pressure per sq. in. is produced. This steam is led through a heat-lagged pipe to the producer plant itself. By referring to Fig. 2, the general arrangement of the generating plant may be seen and the paths of the incoming and exhaust gases located. By this cooling, the gases are effectively silenced, as well as, at the same time, being made to serve a most useful purpose. A plentiful supply of cooling water for the cylinders is required, and this water is circulated by pumps and effectively cooled in a Heenan's patent water cooler, supplied by Heenan & Froude, Ltd. (Worcester). This ingenious machine, as may be readily appreciated by an inspection of Fig. 1, is of small size, considering the work it has to do. It consists of a cylindrical casing with horizontal axis. The lower part of the casing contains the water. In this chamber are a number of concentric metal plate cylinders fixed about  $\frac{1}{8}$  in. apart, and in several sections. These are carried on a shaft, which is revolved at a slow rate, are open at both ends, and are all of the same length. The lower half of the cylinders dips into the hot water in the casing, and as the cylinders revolve, a thin film of moisture on each side of each plate is carried into the upper portion of the casing. A cased fan is fixed at one end of the machine, and induces the air through the annular spaces between the cylinders. The water to be cooled is circulated by a centrifugal pump, driven by an electric motor arranged to drive the cooler by belt. The air and water are passed through

the cooler in contrary directions, and baffles are fitted for the air and water to ensure proper distribution, and in order to increase the efficiency of the machine. As the cylinders revolve, the thin film of water on the surfaces of the cylinders is partially evaporated, and this evaporation causes the heat given to the cylinder plates by the warm water to be rendered latent. Heat is also extracted from the water by conduction. The amount of water evaporated varies according to the temperature within the limits of 1 to 3 per cent. of the amount of water circulated. This is made up automatically by connecting the ball-cock supplied with the machine with the ordinary fresh-water supply. There are no other water losses. The air leaving the cooler is entirely free from loose moisture.

In Fig. 2 will also be noticed the motor-driven air compressor and the three air-storage tanks, where air at 300-lb. pressure per sq. in. is stored for starting the gas engines. One set is now kept running continuously, and the other, though put in as a stand-by, now runs factory hours (6 a.m. till 6 p.m.). It is the practice to clean two cylinders every three weeks, as this keeps the engines in perfect order, and no stoppages have been experienced for some considerable time. On test the sets ran for the prescribed period of thirteen weeks without a stop. The pressure and thermal qualities of the producer gas are continuously recorded in the engine room itself. The heat value is determined by a meter supplied

FIG. 1.—HEENAN PATENT WATER COOLER.

by Parkinson & W. B. Cowan, Ltd. In this instrument it is arranged that the heat of a gas flame causes the expansion and contraction of a small oil column, and this in turn acts on the secondary mechanism.

Referring now to Fig. 3, the general lay-out and arrangement of the producer and recovery plant may be seen. The whole of this plant was supplied by the Power Gas Corporation, Ltd. (Stockton-on-Tees), and consists of two units, each rated at 1,250 I.H.P. The producers are of the Mond pressure type, provided with water bottoms and fitted with wide fire bars of the standard pattern. The coal—a cheap, bituminous variety, mined only a short distance from the station—is well screened, and fed into a hopper, from which a bucket-conveyor lifts it to bunkers erected on a steel framework over the producers, into which it is discharged as required. The fire in the producers is kept some  $4\frac{1}{2}$  ft. thick and supplied with hot saturated air and extra steam. The proportions of each necessary to give the richest gas, in respect of ammonia for the purpose of forming the maximum amount of ammonium sulphate, and at the same time for preventing the formation of clinker, were determined by experiment, and now the amount of live steam is adjusted so that the temperature of the incoming air before it is superheated is  $85^{\circ}\text{C}$ . An excess of steam has this effect by keeping the temperature of the fire low. On the top of the producer bells are a number of heavy iron balls, each with a diagonal hole. These balls rest in seats, and when one is removed by a rod through the hole, the fire may be seen, or the rod may be used to poke the fire without permitting the escape of gas, while the balls also act as safety valves.

FIG. 2.—GENERAL ARRANGEMENT OF THE GAS GENERATING-PLANT IN THE ENGINE-ROOM AT THE ACCRINGTON ELECTRICITY WORKS.

FIG. 3.—GENERAL ARRANGEMENT OF PRODUCER GAS AND BY-PRODUCT RECOVERY PLANT AT THE ACCRINGTON ELECTRICITY WORKS.

The gas from each producer is led through a tubular superheater to a collecting main. The superheater consists of concentric tubes, and the hot producer gas in the annular space warms up the incoming saturated air, which is passed through the fire in the producer bell, and is at the same time itself cooled. Dust catchers are arranged at the base of the superheaters, where the fine dust carried over from the fires is collected and may be periodically discharged. The temperature of the gas in the collecting main is about  $400^{\circ}\text{C}.$ , and it is then passed through the first washer. This consists of an oblong enclosure over a water trough in which are two revolving "dashers," shaped like paddle-wheels, which produce a fine spray and cause the fine particles of tar in the gas to be deposited in the water trough and to escape through lutes at the sides into an external trough, from which it is removed by ladles to suitable containers. The gas is next led to a washer of similar construction, except that instead of ordinary water being used, it is slightly acidified by the addition of about 2 per cent. of sulphuric acid. A chemical reaction takes place here, so that a solution of ammonium sulphate is formed. This is drawn off at intervals and conducted to a stock tank, and at the same time an equal volume of fresh acidulated water is added, so that this process, like all the others, is continuous. The gas then passes through a spray arrester to two vertical coolers, in which, during its ascent, it meets a fine, falling, cold-water spray, and deposits most of the tar. It is then led to a governor like a small gasometer, which, by its rising and falling, controls the supply of compressed air, obtained by Roots' blowers, to the producer bells through a butterfly valve by allowing a varying quantity of the air to escape direct to the atmosphere. The gas is now passed through two centrifugal cleaners, each about 5 ft. in diameter, and containing eight blades. The speed of rotation is 1,400 r.p.m. Here the remaining traces of tar are extracted, and a final cleaning is given to the gas by passing it through a sawdust scrubber, which has not yet become at all dirty, thus showing that the other arrangements are very effective. After this, the gas is metered, and goes by an 18-in. main to the engine-house, where it passes through another small gasometer known as an anti-pulsator.

The air for the producers is put under pressure by the two Roots' blowers already mentioned and passes up a tower, where it meets a broken stream of hot water from the gas-cooling towers. It is thus considerably heated, and also saturated with water-vapour. After leaving these towers, the extra live steam from the boilers in the engine-house is added as mentioned earlier. The mixture is then superheated, by the producer gas in the superheater towers, just before it enters the producer bells. In the shed where the Roots' blowers are situated are also the motor-driven centrifugal pumps for circulating the water through the gas-cooling towers and the water-cooling tower, as well as the air-heating tower. Here, also, are pressure gauges connected to the various parts of the equipment.

The ammoniacal liquor from the stock tank is lifted at intervals by an ejector to a tank in the sulphate-house. From here it is drawn into a steam-heated evaporating tank and boiled until sufficient crystals are produced. These are withdrawn in a nearly dry condition through a hopper in the base, and dried in a hydro-extractor, and then allowed to fall through to the store on the ground floor of the sulphate-house, where they are bagged and sold without further preparation. No pumps are placed in any part of the plant where they are liable to corrosion by chemicals. Some trouble was at first experienced from this cause in the absorption plant, where the ammoniacal liquor is separated out, but this plant is now entirely lead lined and gives no trouble.

We understand that about £5 per week is at present realised by the sale of tar, though the installation of a pitch-making plant at an early date is contemplated, as pitch should fetch something over £2 per ton, compared with 10s. per ton for crude tar. The revenue from the sale of sulphate is between £40 and £50 per week, at the current market price of about £12 10s. per ton. The amount of coal used is about 85 tons per week, being  $1\frac{1}{2}$  lb. per unit generated. Between 12,000 and 13,000 units per week are generated by the gas plant, which therefore runs at a load factor of over 40 per cent., but, reckoning one set as a stand-by, the load factor on the remaining set approaches 100 per cent. An additional twenty-four hour load of some 350 kw. for a paper works will shortly be connected.

The cost of the entire equipment without buildings or foundations was about £23,000, or with cost of containing walls, &c., necessary on account of the nature of the ground, the amount is raised to £28,000 or £14 per h.p.

Besides the gas plant, the station is interesting on account of the dust destructor combined with it, which gives good results. The clinker formed is ground in a mill for mortar. The lighting of the streets in Accrington where there are tramways, is effected in an efficient and economical manner by the use of metal filament lamps on batterns supported on the guard wires over the trolley lines. The position of the lamps is thus easily adjustable to suit local circumstances, so as to give a good light at crossings and at junctions of side streets, &c.

Our thanks are due to Mr. Gray for kindly affording us facilities for viewing the entire plant.

## ROTARY SNAP SWITCHES

A LOW-PRICED line of rotary switches with certain distinctive features has recently been placed on the market by the British Thomson-Houston Co., Ltd. (77 Upper Thames Street, E.C.). The weight of moving parts has been

FIG. 1.—FIVE AMPERE D.P. ROTARY SNAP SWITCH.

reduced to the minimum consistent with durability and proper current-carrying capacity. Bases of the best quality porcelain and ebonised handles with self-contained springs are used. By the employment of flat binding posts, easy access to the binding screws is obtained, in however confined a position the switch may be fixed, as the screw-driver works from the front of the switch, at right angles to the wall. The danger of cutting the wires at the screw contacts is also removed. These switches are supplied with both nickel (fibre-insulated) and porcelain covers. Single and double pole switches are supplied for 100-250 volts and 250-600 volts, with current-carrying capacity ranging from 3-20 amperes, and with or without indicating dial in the cover. The illustration, Fig. 1, shows the interior of one of the double-pole rotary snap switches for 5 amperes. There is a three-way switch in three sizes—3, 5, and 10 amps., 100-130 volts; or 1, 3, and 5 amps., 200-250 volts—and a three-circuit rotary switch for automobile lighting, suitable for use on voltages up to 250, and supplied with or without indicating dial. It is arranged with three circuits, so that the headlights, tail-light and interior lights of a motor-car can be switched on or off separately or together. The condition of the circuits is shown by an indicator for that purpose. For heating and cooking apparatus a series-parallel, three-heat switch with the usual type of indicator may be obtained for currents up to 10 or 20 amperes, and for voltages up to 250. A switch of this type is shown in Fig. 2.

FIG. 2.—SERIES PARALLEL THREE HEAT SNAP SWITCH FOR RADIATOR CIRCUITS.

**Voltage Rating of Mazda Lamps.**—In the early days of the metal filament lamp, it was a fairly general practice for electric light users to employ lamps rated about 5 per cent. above the supply voltage. The excuse for this was that the pressed filament tungsten lamps were fragile, and that by under-running them their life was increased, and they were enabled to withstand the slight fluctuations in the supply voltage. The British Thomson-Houston Co. (Mazda House, Upper Thames Street, E.C.) ask us to state that their lamps should be used rated at the actual voltage of the supply, without fear of premature failure. Although under-running may slightly lengthen the life of the lamp, they maintain that the saving is more than offset by the lower efficiency of the lamp when run below voltage.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,353.

A three-phase induction motor with squirrel-cage rotor runs clockwise. Another similar motor, from the same makers, runs anti-clockwise; both are coupled up to a star delta switch, and to same sketch, which is standard. Having a quantity of these motors running, it is desired not to change over the mains at the starter. Can the right rotation be obtained by altering any of the six connections at motor end, and run satisfactorily with load?—"MOTOR."

(Replies must be received not later than first post, Sept. 4th.)

### ANSWERS TO No. 1,351.

A factory is to be driven electrically by motors aggregating about 200 h.p., varying in size from 3 to 50 h.p., and including a few of which the speed has to be varied. The only supply available is at 240 volts, 50 cycles, single phase. What class of motors and control would it be best to employ?—"P."

The first award (10s.) is made to "W. H." for the following reply:—

First consider the scheme if the single-phase A.C. supply were used. As variable-speed motors are required in some cases, ordinary single-phase motors with slip-ring rotors will not be suitable. The reason is that as resistance is inserted in the rotor circuit, so does the overload capacity of the motor become reduced, and, if any considerable speed reduction is required, the motor will not even withstand full load unless a very large and consequently expensive machine is used. There will, in addition, be the reduction in the efficiency of the motor, due to the losses in the resistance inserted in the rotor circuit. This means that single-phase commutator motors will be necessary, with their liability to trouble in small sizes, and also their poor efficiency. The remaining machines would be made up of squirrel-cage and slip-ring motors. The squirrel-cage motors could only be installed for small horse-powers and very low starting torques. Even the slip-ring motors would require friction clutches for starting up against high initial torques, thus entailing additional expense.

The efficiency and power-factor of a large number of small single-phase motors would also be very poor, especially when working on low loads. A much more satisfactory method would be to instal a motor-generator set consisting of a single-phase motor of about 200 h.p., driving a D.C. generator having a capacity of 135 kw. at, say, 440 volts, thus allowing a load-factor of 75 per cent. The generator could be either shunt or compound, depending on the nature of the load.

This scheme may have a slightly higher first cost, but all the motors installed in the factory could be built to suit the various conditions in the way of speed, speed variation, and type of winding—shunt or compound—for light or heavy starting torque. There would probably be some gain in overall efficiency, and there would certainly be a reduction in the cost of wiring, as compared with the single-phase system. Some disadvantage may be incurred by the necessity for running the motor generator set, even when only a few of

the factory motors are running, such as on overtime. If small factory extensions were in view, it would be advantageous to instal a slightly larger motor generator set. In the case of extensive additions, a second motor generator set could be installed.

The second award (5s.) goes to "M. M.," whose reply in abbreviated form is given below:—

Single-phase induction motors are not suitable for starting up under load, nor for variable speed; and although much is claimed for repulsion motors, such machines are costly and complicated. On the other hand, induction motors with squirrel-cage rotors often give every satisfaction, and stand up against any amount of hard usage. Two systems should be provided: (1) single-phase direct from the supply, and (2) either three-phase or direct-current from a motor generator set, with a single-phase synchronous motor. If most of the work is to be done at varying speed, shunt-wound motors with inter-poles will be best, as the control is simple, and commutating troubles are now negligible. A.C. slip-ring motors with adjustable resistance in the rotor circuit are inefficient, and the various other arrangements either give prearranged speeds with little grading, or are too complicated and expensive. It appears attractive at first sight to have a complete single-phase installation throughout, but single-phase motors are higher in first cost and lower in efficiency than three-phase motors.

## ELECTRIC HEATING AND COOKING

A COMPREHENSIVE list of "bright, glowing electric fires" (Townshend's system) and cooking apparatus, known under the name "Calor," has just been sent us by Townshend's Art Metal Co., Ltd. (Ernest Street, Holloway Head, Birmingham, and 62 Holborn Viaduct, London, E.C.). The heating element for all "Calor" appliances, with the exception of electric fires, consists of resistances of a special alloy wound on asbestos-covered mica strips, insulated with further strips of mica, and protected with sheet-iron casing against mechanical injury. In the case of toasters and grillers the sheet-iron casing is dispensed with and a perforated iron case protects the elements and allows a fierce heat, so essential for this purpose, to be directed where required. The heating element is run at a comparatively low temperature, which gives it a long life. When burnt out, however, the element can be renewed by simply removing

HEATING ELEMENT AS SENT OUT FOR REPLACEMENT.

a few screws, and new elements, ready wound with resistance wire, are obtainable at a trifling cost.

The element for electric fires consists of resistances of a non-oxidisable alloy mounted on a special base composed of a clay of a highly refractory nature, which quickly becomes red-hot. The illustration shows an element as sent out for replacement. This is made in various shapes and sizes suitable for any patterns of case, from which there are a large number to choose. Among the other appliances listed are irons, toasters, kettles, ovens, boiling rings, hot-plates, &c. A special feature of the ovens lies in the way the heating element is placed in a separate chamber at the bottom, from whence the heated air ascends between the double sides of the oven to the top, then strikes downwards again through holes in the sides near the bottom, and then upwards again. Three or four heats are provided, and a separate boiling ring may be used at the top to effect a preliminary warming and to give a final browning.

## CATALOGUES, PAMPHLETS, &c., RECEIVED

**DYNAMOS AND MOTORS.**—A new publication dealing exclusively with open-type dynamos and motors for outputs between 19 h.p. and 1,750 h.p., has just been issued by Bruce, Peebles & Co., Ltd. (Edinburgh). Besides giving a full detailed specification it contains a number of half-tone illustrations of interesting machines and equipments, as well as approximate weights and dimensions of the different frame sizes, lists of ratings with technical data, &c. The standard pressures are 115, 230, and 500 volts, but the machines can be designed to run on pressures as low as 100, 200, or 400 volts, or as high as 125, 250, or 600 volts, without any variation in speed or output, except in the case of some four pole machines. All ordinary requirements are covered by four standard types of machines, but of course any special conditions can be met. The standard types are (a) half-coupling and one bearing; (b) half-coupling, one bearing, and horse-shoe bed plate, or three separate sole plates; (c) two bearings and bed plate, or four small separate sole plates for direct-driving through a flexible coupling, or for belt or rope drive, and (d) three bearings and bed plate for belt or rope drive. The care with which every electrical and mechanical detail is thought out and put into practice should be well known to our readers, and is evidenced by the long list of important customers contained in this pamphlet. It might be mentioned that smaller direct-current machines form the subject of a separate list, already noted in our columns.

**DYNAMOS AND MOTORS.**—A new list dealing with D.C. dynamos and motors has just been issued by Simplex Conduits, Ltd. (Garrison Lane, Birmingham). Particulars of machines from 1/100 h.p. to 44 h.p. are given, and we understand the company holds large stocks of these machines at its works. Illustrations and some notes on motor-generators for cinematograph purposes, vertical motors, and large generators up to 1,000 kw. are also given. Dimensions and weights of the machines and prices of suitable control gear are included in this catalogue. The motors are all supplied either semi-enclosed, enclosed ventilated, or totally enclosed. Each type is fitted with ring lubrication, and special attention has been given to the design of the brush gear. All 4-pole machines are of the inter-pole type and each part is standardised, so as to be readily replaceable, and of the usual Simplex quality. In the intermediate sizes from 1/2 h.p. and up to the 6-pole machines, the end plates of the motors are so arranged that they may be turned through 90° or 100° should it be necessary for the machines to be run in a vertical position. Amongst the illustrations included in the catalogue is a very interesting example of a 110-kw. generator, seven of which have recently been supplied for a large Atlantic liner.

*Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."*

**IRONCLAD SWITCHGEAR.**—A pamphlet from A. Reyrolle & Co., Ltd. (Hebburn-on-Tyne), illustrates some ironclad switchgear for controlling the power supply to a large cement works in Canada. The main switch is for three-phase current and has a capacity of 3,000 amperes. It has a two-pole time-limit overload and no-volt release.

**"MERZ-PRICE" PROTECTIVE GEAR.**—Another pamphlet from the same firm describes the well-known "Merz-Price" system of automatic protection for high-pressure circuits.

**SILICA LAMPS FOR POWER CIRCUITS.**—This is the title of the latest literary production of the Westinghouse Cooper-Hewitt Co., Ltd. (80 York Road, King's Cross, N.). These lamps will burn in parallel on 500 volts, and will stand pressure fluctuations of 10 per cent. up or down without variation in operation, so that they should find use in car sheds, ship-yards, and similar industrial buildings and yards. The burner is in the form of an inverted U, and is lighted by means of a heater on a horn projecting from the luminous tube proper, so that tilting is unnecessary. The heater is cut out immediately the burner is lighted.

**ALUMINIUM FOR RAILWAYS.**—A leaflet from the British Aluminium Co., Ltd. (109 Queen Victoria Street, E.C.), makes some suggestions as to the utilisation of aluminium in electric railway working. A section through a 30,000-volt aluminium cable and particulars of some designs of aluminium collector bow strips, motor field coils, rolling stock, construction, &c., are given.

**CONDUITS AND CONDUIT FITTINGS.**—A new catalogue, cancelling all previous issues, has just been produced by Electrical Conduits, Ltd. (18 Bennett's Hill, Birmingham). The numbers of some of the fittings have been altered, and prices

revised to agree with those of other standard makes. As well as a complete range of conduits, numerous fittings, including switches, plugs, junction boxes, and other accessories, are conveniently listed. Special attention is drawn to the "HIC" patent grip fittings illustrated in *ELECTRICAL ENGINEERING*, Vol. VIII., p. 546, October 3rd, 1912. Gas, galvanised, and steam tubes and fittings are included in the list.

**FLEXIBLE COUPLINGS.**—A new list from the Power Plant Co., Ltd. (39 Brandville Road, West Drayton, Middlesex), gives particulars and detailed illustrations of the patent reversible insulating couplings made by this firm. The couplings are made in several standard types, and special combinations can be arranged to suit special requirements.

## LOWERING GEAR FOR METAL FILAMENT LAMPS

SOME idea of the raising and lowering gear for the metal filament lamp street lighting in Fulham may be gathered by those who have not seen it from the accompanying illustration. In the foreground is a double arm post, and in the background a single arm post; in this case the lamp is lowered for cleaning, &c. About 200 brackets and sets of gear for this installation were supplied by the London Electric

METAL FILAMENT LAMP STREET LIGHTING IN FULHAM.

Firm (George Street, Croydon). The gear is of their well-known positive acting weight-relieving type, and the winches are of their self-sustaining type. The brackets are of the rectangular type, with pulleys and tubes fitted inside to prevent the rope from touching the electric cables, which are also inside.

## UNIVERSITY AND TECHNICAL COLLEGE ANNOUNCEMENTS

The next session of the University of Leeds begins on September 30th, when the entrance examination will be held at 10 a.m. and 2 p.m. The prospectus, dealing with the departments of electrical, civil, mechanical, and mining engineering, and coal gas, fuel, and metallurgy, may be had free on application to the secretary.

The new course at the Crystal Palace School of Practical Engineering will commence on Wednesday, September 10th. Intending students should attend the previous day between 10 a.m. and 1 p.m. for examination. Particulars of the various courses will be forwarded to those applying to the Registrar, School of Engineering, Crystal Palace, S.E.

HIGHEST  
QUALITY!

SPECIFY

**'IGRANIC'****SWITCHGEAR**

IGRANIC ELECTRIC CO. LTD.

BEDFORD and LONDON.

**TELEPHONY AND TELEGRAPHY  
(INCLUDING WIRELESS)**

According to a return just published, by an order of the House of Commons, the number of trunk calls (excluding calls to and from the Continent) has increased fairly uniformly from 13,467,975 in 1903-4 to 35,815,959 in 1912-13. At the same time, the mean number of trunk lines in use increased from 1,363 to 3,180, and the double-wire mileage increased from 49,100 to 117,900. The average number of calls per trunk circuit per day was 34.1 in 1903-4, rising to a maximum of 36.9 in 1905-6, and falling to a minimum of 33.0 in 1908-9. After this the number rose to 39.6 in 1911-12, and in 1912-13 was 38.8. The estimated average operating cost per call varied as follows, from 1907-8 to 1912-13 inclusive: 1.27d., 1.36d., 1.37d., 1.29d., 1.23d., 1.26d. From 1903-4 to 1912-13 the receipts from inland trunk calls increased from £325,525 to £912,342, and the average fee per call increased from 5.8d. in 1903-4 to 6.1d. in 1911-12 and 1912-13. It is also stated that the busy-hour traffic usually amounts to about one-fifth of the total traffic between 8 a.m. and 8 p.m. The average time a trunk circuit is held in connection with a three-minute call ranges from three-and-a-half to six minutes, while if six-minute calls be included, the time ranges from four-and-a-quarter to seven-and-three-quarter minutes.

The Postmaster-General has notified a number of telephone users in Douglas, I.O.M., that their instruments will be disconnected in consequence of the Town Council's having refused what he states he considers to be the generous terms he has offered for wayleave over municipal property (£5 per annum). The Chamber of Commerce has approached the Governor of the Isle of Man on the matter, and he has undertaken to communicate with the Postmaster-General. The rent demanded by the Council was £25 per annum.

At the general meeting of the Marconi Co., which took place on Friday last, the report and accounts, given in our last issue, were agreed to. The Chairman, Mr. G. Marconi, announced that the Company has just obtained a fifty years' concession for connecting Rio de Janeiro and other centres in Brazil with Europe. As soon as possible, a Brazilian Company will be formed for the purchase from the parent Company of its long-distance rights, together with the concession. The new Company will no doubt enter into an agreement with the American Co., by which the station to be built at Para will carry on a service with New York and other parts of the United States. The Managing Director, Mr. Godfrey Isaacs, in the course of his speech, said: "... Whatever you have read in the papers as having been done by wireless telephony, the Marconi Co. has done more. But until the Marconi Co. is prepared to say exactly what definite results in a practical way can be obtained from wireless telephony, it will remain silent. We shall, perhaps, at an early date be able to turn wireless telephony to practical commercial account, and it will then be time enough to speak."

Rules have been issued in Germany with regard to stations erected to receive the wireless time-signals which are sent out by the Norddeich wireless station. The apparatus has to be adjusted to receive waves only of 2,000 metres length; and everything, with the exception of the handle for tuning, the detector switch, and the telephone receiver, must be encased, and closed with a seal, so as to be inaccessible to the owner.

The last issue of the *Telefunken Zeitung* contains a great deal of interesting matter in commemoration of the tenth anniversary of the Company's establishment. Among other articles are reviews of the present extension of long-distance wireless telegraphy, and of the ten years' work of the Company; descriptions of the wireless telegraph installation on the s.s. *Imperator*, and the erection of the wireless station at Kamina (Togo), illustrated with interesting views; and excellent portraits of Count von Arco, Dr. Adolf Franke, and Mr. Paul Mammoth.

Construction work has begun on the large wireless station at Caimito in the Panama Canal Zone, says the *Electrical World* (New York). It will be similar to the station at Arlington, and the aerial will be supported on three 600 ft. towers, arranged in a triangle, 900 ft. apart. The nominal radius for sending and receiving will be 3,000 miles, so that communication with Washington can be maintained.

The official tests of the system of wireless telegraphy invented by the Japanese electrician, Mr. Torikata, in which satisfactory results were obtained at distances of sixty miles, have resulted in the Japanese Government ordering all shipping companies subsidised by it to instal the apparatus on their principal vessels. It is stated that patent rights have been secured in Japan, France and this country, and are pending in Germany and the United States.

On the 21st inst. the Saseho-Darien cable failed, and on the following day notice reached us that secret language was again admitted in telegraphic correspondence with Crete. The Greek office notifies for general information that there is no telegraphic communication with Gumuldjena and Xanthi. —On the 22nd inst. the Salonika-Lemnos cable became interrupted, and telegrams are being sent via Malta at senders' risk. —The Great Northern Telegraph Co., Ltd., announces that on and after the 1st of September next the rates to the undermentioned places in the Far East will be as follows: Hongkong, China and Manilla, 3s. 6d.; Japan and Formosa, 3s. 11d.; Dutch Indies, 3s. 7d.

**ELECTRIC TRACTION NOTES**

The Dublin United Tramways Co. has, during the past week or two, been experiencing some trouble with its motor-men and conductors, some of whom came out on strike; but no difficulty has been experienced in obtaining a sufficient number of men to keep the service running. On Tuesday, however, a number of the Company's cars were deserted by the men in charge of them, who left them standing in the streets, and as the result of the fresh outbreak the Company decided not to run any cars after dark. The Transport Workers' Union, which is at the back of the trouble, has also made a demand for an increase of wages in respect of the Ashton tramway employees and the men in the employ of the Stalybridge, Hyde, Mossley, and Dukinfield Joint Tramway Board.

The Greenock Corporation has decided to give notice of its intention to acquire the Greenock and Port Glasgow Tramways Co. at the end of its lease on May 15th, 1914.

The Llandudno & Colwyn Bay Electric Railway Co. has arrived at an agreement with the Colwyn Bay Council to pay £6,500 towards the cost of the purchase of land to enable the Company's lines to be extended to Old Colwyn. The extension of the line to this point has been a matter of much discussion and negotiation between the Company and the Council for many years past.

The horse tramways in Stirling are the only ones of the kind now in existence in Scotland, but Messrs. Balfour, Beatty & Co. are proposing to take over the horse tramway company with a view to converting the lines to electric traction, provided the new company about to be formed is also able to acquire the Corporation's electricity undertaking.

There was a net profit of £3,792 upon the past half-year's working of the Aberdeen Suburban Tramways Co. It is proposed to add £2,000 to renewal and depreciation account, and to pay a 24 per cent. dividend. The directors have under consideration the running of trolley-buses.

The accounts of the Newport (Mon.) Tramways for the year to March 31st, show a deficiency of £2,327, after meeting capital charges amounting to £10,014. It was estimated at the commencement of the year that the loss would be £2,470. During the year no less than £9,470 were spent upon repairs to the permanent way and the reconstruction of cars.

The Standardisation Committee of the Electric Vehicle

# "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

## Specifications Published August 21st, 1913

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

17,150/12. **Thomas Transmission System.** J. G. P. THOMAS and THOMAS TRANSMISSION, LTD. The two dynamos and the prime mover are connected through a balance gear, so that the three shafts are in line without the use of flexible couplings. Each machine and the balance gear forms a complete independent unit before assembly. One figure.

17,517/12. **Temperature Control in Freight Vans.** ELDERS & FYFFES, LTD., A. W. PRIM, and F. W. ROPER. An axle-driven dynamo feeds both heaters in the air casings, and fans. A uniform temperature is maintained by thermostatic control. Seven figures.

17,980/12. **Resistances.** J. ROTHMAN and FERRANTI, LTD. Compressible resistances are made of graphite, and nickel plates so arranged that the + temperature coefficient of the nickel balances the - temperature coefficient of the graphite. Four figures.

23,273/12. **Variable Speed Dynamos.** H. LEITNER. The machine has its field coils wound in several sections, which are connected in parallel when the machine is to be used as a shunt dynamo and in series with one another and the armature when it is to be used as a motor. The armature may have two sets of windings connected in parallel or in series, according as the machine is used as a series motor or shunt dynamo. Two sets of accumulators may be arranged in series or parallel under these conditions. Four figures.

25,991/12. **Railway Signalling.** H. W. FIRTH and F. W. LEAKE (G. E. Railway). To prevent a signal from being permanently locked in the danger position due to abnormal conditions in the locking circuit, an alternative lock-releasing circuit is provided. This circuit is controlled by the signalman through a protected switch. The lock-indicator mechanism is at the same time screened by a shutter, which, together with the emergency switch, can only be restored by the electrician in charge. Six figures.

27,651/12. **Fire-proof Insulation for Cables.** J. LOEWENTHAL. The cable is passed through an electrolytic bath of aluminium salts, and connected as the cathode, so that a smooth, adhering, fire-proof insulating layer of aluminium compounds, especially aluminium hydroxide, is formed on the cable. One figure.

29,291/12. **Starting Internal Combustion Engines.** ERNST EISEMANN & Co. and E. EISEMANN. For multi-cylinder engines there is a main magneto and an auxiliary magneto put into operation by cranking while the main magneto is automatically disconnected. The primary of the auxiliary magneto contains a make-and-break switch, actuated by the cranking and a switch in the same circuit actuated by the shaft of the main magneto. The circuit is broken by this switch except when the particular piston has passed its dead point. One figure.

7,575/13. **Self-starters for Internal Combustion Engines.** W. C. S. CHAPMAN (A. D. Chapman, South Africa). Compressed air is used, and the valves are electrically controlled through the ignition circuit. One figure.

## Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free. Summaries of some of the more important of these patents will appear in our next issue.

**Arc Lamps:** ROUBAL [Electrode manufacture] 10,210/13.  
**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** HANDCOCK, DYKES and DUDELL [Change-over switchgear operated by resonance] 1,395/13; CORTEZ-LEIGH and BROUGHALL [Sealing cable terminals and connections] 7,996/13.

**Dynamos, Motors, and Transformers:** WHITE, DAWSON and HOUGHTON [Brush holders] 18,145/12; PLOHL [Frequency changing] 18,893/12.

**Ignition:** BELL [Engine starting] 20,802/12; ENTZ [Engine starting and lighting for automobiles] 25,386/12; VANDERVELL and MIDDLEY [Engine starting] 4,522/13.

**Incandescent Lamps:** HARRISON, 24,571/12; VEREINIGTE GLANZSTOFF FABRIKEN [Filaments] 2,992/13; A.E.G., 14,048/13.

**Instruments and Meters:** GOTTSCHALK and H. ARON ELEKTRICITÄTS-ZÄHLERFABRIK [Energy meters] 18,809/12; SIEMENS BROS. (Siemens & Halske) [Step-by-step rotation of an armature] 1,277/13.

**Switchgear, Fuses, and Fittings:** HALL [Automatic reversing gear for motors driving machine tools] 10,599/12; COATES and A. REYROLLE & Co. [High-pressure A.C. switchgear] 18,210/12; KNAPTON [Switches] 27,854/12; SAUNDERS [Shade holder]

3,931/13; GRUNBERG [Fuses] 6,156/13; HANCO [Warp stop motions for looms] 7,570/13.

**Telephony and Telegraphy:** BOULT (Denio G.E. Co.) [Fire-alarm signal-boxes for automatic telephone systems] 18,262/12; TULLETT [Holding telephones] 20,671/12; ANDERSON [Telephone receivers] 2,507/13; TELEPHON APPARAT FABRIK E. ZWIETUSCH & Co. [Telephony] 2,700/13; JENSEN [Telegraphy] 6,292/13.

**Traction:** PEHRSSON [Driving gear for dynamos on vehicles] 18,482/12; WARREN and MORT [Trolley pulleys] 22,696/12; R. DEMPSTER & SONS and BROADHEAD [Trolley arms] 24,263/12.

**Miscellaneous:** WILLMOTT [Solder for aluminium] 19,214/12; LAKE (Fabrik Elck. Zunder) [Winding conducting wires for blasting furnaces into skeins] 20,560/12; B.T.-H. (G.E. Co., U.S.A.) [Annealing iron] 25,902/12; BÜNDGENS [Marine mines] 27,630/12.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Distributing Systems, &c.:** SIEMENS-SCHUCKERT [Remote control of synchronous motion] 687/13; [A.C. motor control] 17,589/13.

**Electrometallurgy and Electrochemistry:** SOC. LEFER [Electrolytic iron] 16,565/13.

**Incandescent Lamps:** SIEMENS & HALSKE, 17,416/13.

**Instruments and Meters:** SOC. DES ÉTABLISSEMENTS GAUMONT [Electro-magnetic balances] 16,034/13; LANDIS & GYR [Magnet core] 17,480/13.

**Telephony:** MEYER [Table instruments] 14,780/13; SIEMENS & HALSKE [Circuits] 17,417/13.

**Traction:** BOIBAUT [Connections for railway vehicles] 13,820/13.

**Miscellaneous:** FRASER [Elevator systems] 13,447/13; SEFFT-LEBEN [Submarine mines] 17,441/13.

## Appeal Against Comptroller's Decision

27,521/11 and 28,260/12. **Cinematograph Targets.** J. B. LE MAITRE. The Comptroller required amendments to these specifications (ELECTRICAL ENGINEERING, July 31st, p. 446). This decision is now appealed against.

## Expiring and Expired Patents

The following Patents expired last week, after a life of fourteen years:—

16,960 of August 21st, 1899. **Pressure Operated Liquid Rheostat.** C. DE KANDÓ. This patent covers a construction of a liquid rheostat in which the height of the liquid between the terminal plates is automatically determined by the pressure of compressed air. The air admission is regulated by a throttle valve, while an automatic escape valve comes into use when the resistance is to be increased. An additional valve controlled by a float determines the final short-circuiting of the plates.

16,961 of August 21st, 1899. **Traction Motors.** C. DE KANDÓ. The frame on induction motors direct coupled to the road wheels is cut away on the underside, so that the diameter of the armature can be a maximum.

The following Patent expires during the current week, after a life of fourteen years:—

17,386 of August 28th, 1899. **Snap Switches.** M. GUETT. Constructional details are covered by this patent, including a hinged contact carrier, and a hinged working lever, both connected by a spring. On the lever is a shoulder, and on the contact carrier a lip so arranged that it can engage with the shoulder. Seven figures illustrate the construction.

The following are the more important Patents that have become void through non-payment of renewal fees.

**Arc Lamps:** A. WUNDERLICH and G. A. HUGHES (London Elec. Firm) [Span wire construction] 9,707/08.

**Dynamos and Motors:** B.T.-H. Co. (G. E. Co., U.S.A.) [Commutator insulation] 10,795/06.

**Switchgear, Fuses and Fittings:** EVERED & Co. and S. EVERED [Switch lamp-holder] 10,395/03; F. CONRAD [A.C. overload and reverse current circuit-breaker] 10,172/06; THAMES IRONWORKS Co. and W. H. FLOOD [Quick make and break switches] 9,697/08.

**Telephony and Telegraphy:** S. EISENSTEIN [Wireless transmitting system] 10,019/08; [Condenser] 10,023/08.

**Traction:** W. R. SYKES [Signalling: Track treadles to ensure that same number of vehicles leaves a section as enters it] 10,558/04; C. DE KANDÓ [Cascade connections] 10,648/04; ELEC. & ORDNANCE Co. and R. F. HALL [Train lighting system] 9,479/06.

**Miscellaneous:** J. MACLEAN [Driving gear for rotary hair-brushes] 10,525/04; P. FROMAGET [Remote control of mechanisms] 9,676/08; C. RUTZICKA [Moulded resistor] 9,762/08.

Association of America has under consideration a proposed charging plug of larger size for the heavier commercial vehicles. An attempt is also being made to adopt a standard list of lamp bulbs, because of the many small variations in voltage ratings and deviations in bulb shapes. The Committee is also going to take up the question of a standard method of testing the rating of solid tyres. Because of the wide variation in compounds used, and of the effect this has on both speed and mileage of electric vehicles, this is a very important question.

## LOCAL NOTES

**Aberdeen: Wiring Rules.**—The Electrical Engineer has been authorised by the Electric Light Committee to revise the Corporation's existing wiring regulations in order to bring them into conformity with the Institution Rules.

**Bromley: Mains for Bulk Supply.**—An inquiry has been held by Mr. W. H. Patchell on behalf of the Board of Trade regarding the deadlock which had arisen between the West Kent Electric Power Co. and the Corporation. The Bromley Electric Light Co. supplies the district, and as its station is now practically loaded up to its full capacity, it proposes to take power in bulk from the West Kent Co. Objection was raised by the Corporation, however, to the routes along which the trunk mains are to be laid. The Corporation named alternative routes, but the electric light company claims that as these alternative routes "are not reasonable," the Corporation cannot refuse to consent to the original route, and this is the matter upon which recourse has now been had to arbitration.

**Dewsbury: Position of Electricity Workers.**—In the course of his annual report, Mr. R. H. Campion, the Borough Electrical Engineer, makes a number of suggestions with a view to ensuring greater co-operation on the part of workmen in the Electricity Department in the general interest of the undertaking. Failing a general co-partnership scheme, Mr. Campion suggests a bonus system on the following basis, applicable to the whole staff, and subject to the payment of a minimum wage:—(1) A bonus to be paid to all men employed in the department; (2) A bonus of 2½ per cent. downwards, according to responsibility, on so much of the amount certified by the Borough Accountant to be the net surplus profit for the next financial year ending March, 1914; (3) Men who are absent, from any cause whatsoever, except annual holidays, have a corresponding reduction made in their bonus; (4) Men engaged during the above period are paid a proportionate sum if they have been employed six months; (5) Any employee going on strike, or discharged for insubordination, forfeits all right to any bonus; (6) Anyone discharged for slackness, or who leaves to better himself, obtains the amount due to him at the end of the financial year. The Electricity Committee, however, has not seen its way to adopt any of the suggestions, but has decided upon giving the workmen an increase of ¼d. per hour.

**Dudley: Proposed Sale of Electricity Undertaking.**—There still seem to be difficulties in the way of the transfer of the Corporation's electricity undertaking to the private company, with whom all the necessary arrangements have now been made. Recent correspondence with the Board of Trade shows that that authority is unable to proceed further with the consideration of the matter until proof has been furnished that notice of the proposed transfer has been advertised in a local paper and in the *London Gazette*, as required under Section 59 of the Corporation's electric lighting Order. According to a local paper it is considered probable that a Board of Trade inquiry will be held, although no reason for this is given.

The agreement is with the Birmingham District Power & Traction Co. and the Shropshire, Worcestershire & Staffordshire Electric Power Co., and the purchase-money is to be the balance of loans raised by the Corporation, which amount to £69,400, the sum of £10,500, and a further sum of £3,334, which latter represents the capital expenditure by the Corporation since March 31st, 1912, which is the date of purchase. The agreement is to be in force for forty-two years, at the expiration of which, or of any subsequent ten years, the Corporation may repurchase by giving six months' notice. The prices to be charged by the Power Co. are not to exceed those at present in force, but with the consent of the Corporation they may be increased at the end of three years. Should

the Corporation withhold its consent, arbitration is provided for.

**Glasgow: Electricity Accounts.**—On p. 461 of our issue for August 7th, we gave the financial result of the past year's working of the Corporation's electricity undertaking. From the report of the Committee we notice that a contract for a 6,000-kw. turbo-alternator has recently been given to the British Westinghouse Co. for the Port Dundas power house, and a similar contract to Messrs. Howden for the Pollokshaws Road station. When these plants are installed, the respective capacities of the two power stations in question will be 36,000 and 30,000 h.p. These are more or less temporary measures pending the erection of the new power station which is now under consideration. In a memorandum regarding the progress of the undertaking during the past twenty-one years, it is pointed out that the average price received per unit has uniformly fallen from 7d. to 1'286d.

**Greenock: Electricity Profits.**—At the last meeting of the Corporation, the Chairman of the Electricity Committee called attention to the satisfactory state of affairs in the Electricity Department, which had enabled it to put on record a net profit for the past year of over £5,000. This makes a total net profit of about £20,000 during the past four years.

**Navan (Ireland): Electric Lighting.**—As the result of a letter from the Board of Trade asking what steps had been taken to carry out the Council's electric lighting Order, the Lighting Committee recommended that application be made for a loan of £7,000 to carry out the scheme. In the Council, however, this recommendation was rejected in favour of one asking the Board of Trade for an extension of time.

**Newport (Mon.).**—There was a loss of £1,093 upon the electricity undertaking for the past year compared with an estimated loss of £1,779. This result is arrived at after writing off £2,471 for superseded plant, and providing £350 for renewal of the battery, in addition, of course, to meeting capital charges. The general progress of the undertaking on the business side has been most satisfactory. The gross receipts show an increase of £1,162, whilst the working expenses increased only by £238.

**Stirling: Proposed Purchase of Electricity Undertaking.**—As mentioned in our Electric Traction Notes, a proposal has been placed before the Council for the purchase of its electricity undertaking in conjunction with the conversion of the existing horse tramways to electric traction.

**Sale of Electrical Fittings.**—Several local wiring contractors have written to the Council regarding the sale of electrical fittings by the Electricity Department, and also as to the drafting of specifications by the Borough Electrical Engineer for intending consumers. Whilst the firms were unanimous that the Council should not indulge in the sale of electrical fittings, there was some difference of opinion as to the desirability of the Borough Electrical Engineer advising consumers, and one firm, at any rate, agreed that it was more satisfactory if this practice were continued. Having considered the matter, the Electricity Committee recommended the Council to co-operate with contractors in securing and extending electrical installations, but that the Electrical Engineer be instructed to adhere to his present practice of advising intending consumers and making out specifications when requested to do so. At the same time it was indicated that the Town Council does not give up in any way its statutory right to supply electrical accessories, although the sale of these for the present is not to be pushed. These recommendations have been adopted by the Council.

**Whitehaven: Combined Lighting and Heating Tariff.**—In view of possible developments in more economical electric lamps, the Borough Electrical Engineer has suggested a scheme whereby, instead of having, as now, a separate meter for heating and cooking purposes, a tariff shall be designed giving a combined rate for lighting, heating and cooking. The Borough Electrical Engineer's report on the question, however, has not been sufficiently considered by the Electric Lighting Committee to enable it to place a recommendation before the Council at the moment.

FOR  
STEAM JOINTS  
USE

JOHN HUDSON & CO.'S SUCCESSORS, Mansell St., London, E.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

### Generating Stations, Sub-Stations, Mains, &c.

**London: Hammersmith.**—High- and low-tension cables; high-tension substation switchgear. Chief Electrical Engineer. September 24th. (See advertisement on another page.)

**Penwortham.**—Electricity is to be substituted for oil power at the Council's sewage works.

**Southampton.**—Steam boiler at electricity works. Borough Electrical Engineer. September 8th. (See advertisement on another page.)

**Waterford.**—Mr. E. M. Lacey, of London, has been appointed Consulting Engineer in connection with the Council's electric lighting scheme.

### Wiring

*The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.*

**Aberdare.**—Cottage hospital at Aberaman. Architect, G. Kenahole, Bargoed.

**Battle.**—It has been decided to light the workhouse by electricity.

**Birmingham.**—New post office and telephone exchange at Moseley. H.M. Office of Works, 42 Paradise Street, Birmingham.

**Bradford.**—Residential school for the blind. City Architect.

**Cambridge.**—Extensions to Isolation Hospital (£8,570).

**Halifax.**—Hospital and pavilion at Sanatorium, Green Lane Hall.

**Kingston-on-Thames.**—New Coliseum.

**London.**—New offices for Board of Trade, Whitehall Gardens. H.M. Office of Works.

**Manchester.**—Electric lighting of the Municipal School of Domestic Economy, High Street, September 3rd. Town Clerk.

Elementary school, Liverpool Road, Irlam.

**Skewen (S. Wales).**—Electric light installation at Free Library. Clerk to Council.

**Stoke-on-Trent.**—Additions to hospital. Architect, E. Jones, 10 Albion Street, Hanley.

**Stretford.**—Infants' school, Victoria Park. Architects, Woodhouse & Howard, 88 Mosley Street, Manchester.

### Miscellaneous

**Aberdeen.**—The installation of portable electric winches at the fish market is under consideration.

**Brazil.**—There is a proposal to construct an underground electric railway in the centre of Rio de Janeiro. This news comes from the Acting British Consul-General in that city.

**Melbourne.**—Alternating- and direct-current recording meters, and maximum-demand indicators. Messrs. McIlwraith, McEacharn & Co., Biliter Square Buildings, London, E.C. September 9th.

Electrical machinery for operating pneumatic tube services. Deputy Postmaster-General, Melbourne. Copy of specification at 72 Victoria Street, or 73 Basinghall Street, London.

**Morecambe.**—The Borough Electrical Engineer has been instructed to prepare a scheme for the conversion of the tramways on the front to electric traction.

## TENDERS RECEIVED AND ACCEPTED

**Liverpool.**—The contract for the lighting of the new Arts Building at the University has been placed with Messrs. Fred Wilkins & Brother, Ltd., 27 to 35 Duke Street, Liverpool.

**London: L. & S.W. Ry.**—In connection with the short article on the contracts for the London & North Western and London & South Western Railways published in our last issue, the Leskole Co., Ltd., inform us that sixteen sets of their electric distance thermometers were specified by Messrs. Kennedy & Jenkin for the power house of the latter line, and have been ordered by the Babcock & Wilcox Co. for superheat readings on the fronts of the sixteen boilers.

## APPOINTMENTS AND PERSONAL NOTES

Some time ago a recommendation by the Dublin Electric Lighting Committee to increase the salaries of the City Electrical Engineer and the Deputy Engineer, as well as the Chief Engineer of the Distribution Department, was postponed for six months. Last week, however, a resolution was moved in the Council to consider the case of the Deputy Engineer, Mr. L. J. Kettle, on its merits, and it was recommended that he be granted an increase of from £400 to £600 per annum by £50 increments. There was considerable opposition to this, particularly on the part of the Lord Mayor, who, according to a local paper, mentioned incidentally that Mr. Mark Ruddle, the City Electrical Engineer, might be retiring within the next two years. Eventually the resolution for the increase of Mr. Kettle's salary was carried by thirty votes to fourteen.

Switchgear fitters and improvers are required by the Igranic Electric Co., Bedford.

Six demonstrators are required for the Model Electrical House at the Ideal Home Exhibition, Olympia. (See advertisement on another page.)

## MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. G. Smith & Son, of 5, Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £73 to £73 10s. (last week, £72 15s. to £73 5s.).

**Record Electrical Co.**—Messrs. Edmiston, Brown & Co., 290 St. Vincent Street, Glasgow, have been appointed agents for the whole of Scotland for the Record Electrical Co., Mr. C. E. Hart having joined this firm.

## COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

**Newcastle and District Electric Lighting Co.**—An interim dividend at the rate of 3 per cent. per annum, has been declared on the ordinary shares for the June half-year.

## NEW COMPANIES

**W. PARSONS & CO.**, Regent Street, Leamington. Capital, £2,000. Electrical and general engineers.

**CLONES ELECTRIC LIGHT & POWER CO.**, Fermanagh Street, Clones. Capital, £2,000.

**PORTARLINGTON ELECTRIC LIGHT & POWER CO.**, 66 Victoria Street, S.W. Capital £3,500. To adopt an agreement with Messrs. Foote & Milne, Ltd.

**BETULANDER AUTOMATIC TELEPHONE CO.**, Marconi House, Strand, W.C.—Capital, £400,000. To acquire from Marconi's Wireless Telegraph Co. the right and patents relating to the Betulander automatic system. We gave particulars of the system in ELECTRICAL ENGINEERING, May 15th, 1913, p. 277.

**LISNASKEA ELECTRIC LIGHT CO.**, Main Street, Lisnaskea.—Capital, £1,000.

**Gas and Electric Mains Breakdown in the City.**—Shortly before midnight on Wednesday last week, workmen repairing the road in Fenchurch Street in the City of London, cut through a large gas main, and also through a 0.5 sq. in. feeder belonging to the City of London Electric Lighting Co. The result was a rather serious fire in the street, which it took some time to extinguish, and the fire spread to a neighbouring Post Office street box as well. Fortunately no interruption to the electric supply was caused, either by the accident itself or during the subsequent repairs. We understand that there are also mains of the Charing Cross Co. in the same street, but these were at a greater depth, and were not damaged.

Cheques to be made payable to THE KILOWATT PUBLISHING CO., LTD., and to be crossed LONDON COUNTY AND WESTMINSTER BANK (Temple Bar Branch).

## SUMMARY

RATHER startling results have been obtained in some experiments upon the effect of globes and reflectors upon the mechanical strength and life of large incandescent lamps. Owing to the rise in temperature of the air surrounding the lamp it is found that the filament becomes less strong, and that the life is considerably shortened. The glass is said to become porous, and this lowers the vacuum. It is recommended that high-candle-power lamps should be run without globes or reflectors. (Page 498.)

A PAPER was read at the meeting of the Iron and Steel Institute in Brussels by Mr. Otto Frick, in which the induction furnace designed by the author was described. It has a rotating cover, small bath inclination, low energy consumption, and a lining giving a regular life of between two and three months. Two of these furnaces are in use in Germany for melting cold scrap. (Page 499.)

THE reports of the Divisional Inspectors of Mines for 1912 which have so far been published show a substantial increase in the number of electrically-driven coal-cutters in use and also in the number of electric safety lamps. Mr. W. Walker (Inspector for the Scotland District) urged the greater use of these lamps. (Page 500.)

THE results of some tests on the crystallising properties of electro-deposited iron are summarised in a Paper by Dr. J. E. Stead and Dr. H. C. H. Carpenter. (Page 501.)

THE patents of special interest to mining electrical

engineers and electrometallurgists which have been issued last month relate to miners' lamps, shaft signalling, the prevention of fires after blasting, and an electrical process for making high-grade pig-iron from phosphorous ores. (Page 502.)

FURTHER particulars of the exhibition of the half-watt Mazda lamp briefly reported in our last issue will be found on page 503.

A CONDUIT pipe clip for surface wiring, an indicating fuse, and a suction cleaner are illustrated and described. (Page 504.)

SOME points relating to air-space telegraph and telephone cables for railway working and other matters are discussed in our Questions and Answers columns. (Page 505.)

WE give particulars of the 110,000-volt transmission lines of the Mississippi River Power Company from their large water turbine power-house at Keokuk, on the Mississippi. The line is some 144 miles long, and consists of a double line on single steel towers about 800 ft. apart. The capacity of the sub-station at St. Louis is 66,000 h.p., and it supplies the railway and lighting companies. (Page 506.)

THE scope of the old International Photometric Commission has been enlarged, and it is now called the International Illumination Commission. Mr. C. C. Paterson (National Physical Laboratory) has been elected first Hon. Secretary. (Page 507.)

ENORMOUS progress has been made in the extension of telephony in Canada. (Page 507.)

REFERENCE is made in our "Electric Traction Notes" to American practice in connection with frequency-changers.—An all-night service is started to-day on the Manchester tramways.—In spite of the strike riots in Dublin, the tramway service has apparently been maintained. (Page 507.)

THE specifications published by the Patent Office last Thursday include one by the A.E.G. for a metal filament lamp, in which, by the introduction of a foreign substance into the bulb an atmosphere of oxygen at low pressure is produced. An increased efficiency is obtained. In another specification by F. and F. L. Harrison a renewable metal filament lamp is described, while F. Coates and A. Reyrolle & Co. claim a no-voltage release for high-pressure switchgear without the necessity of intermediate transformers. An important patent for a submarine telegraph relay by S. G. Brown has expired. (Page 508.)

A SMALL station with two 100 h.p. semi-Diesel sets has been started at Portishead, near Bristol, by a private company.—The Aberdeen accounts show very large increases in the power and heating loads.—The electricity supply at Bognor, which will be furnished by the Gas Company, is expected to be started up at the end of the month. (Page 509.)

A LOAN of £79,700 has been sanctioned for extensions of the Sheffield Electricity Works.—Smaller ex-

tensions are to be made at Hornsey, Accrington, Haslingden, and Bingley (Yorks).—It has been decided to extend the generating stations at Belfast and Newport (Mon.).—Concessions for electricity supply have been granted to a number of gentlemen in Cuba.—The proposed electrification of some Argentine railways is reported. (Page 509.)

### THE INFLUENCE OF GLOBES AND REFLECTORS ON THE LIFE OF METAL FILAMENT LAMPS

USERS of metal-filament lamps of high candle-power, such as are employed for street lighting, may have noticed considerable differences in the life of such lamps when enclosed in different forms of globe. A similar effect, though not so pronounced, is often observed with lamps of low candle-power. It appears that this is due to the different temperatures of the air immediately surrounding the lamp, and a Swedish engineer, Herr Gustaf Sundén, of Ludvika, has carried out experiments over a very long period in order to investigate this. The experiments are described in the *Elektrotechnische Zeitschrift* of August 28th, and are of a

SECTION AND ELEVATION OF 100-1,000 C.P. LAMP FITTED WITH SPECIAL HOOD.

most conclusive nature. A large number of new drawn filament lamps of first-class make were run under three different conditions. One group was run without globes or reflectors

of any kind under normal conditions in a room in which the air temperature was constant at 20° Centigrade. The second group were run in a heat-insulated metal chamber in which a steady temperature of 200° C. was reached in a very short time. The third group was run in the open and cooled by flowing water with a constant temperature of only 2·5 C.

The lamps were taken after various durations of burning, and tested on a Müller impact apparatus for determining their mechanical strength. The results are given in the form of curves. The lamps burning under flowing water showed absolutely no decrease in mechanical strength after a hundred burning hours, the curve being a perfect straight line. Those burning at the room temperature of 20° C. showed a decrease in mechanical strength of 25 per cent. after 100 hours, and 37·5 per cent. after 200 hours, the reduction in strength being less rapid as the lamp burned until the life of 2,000 hours was reached. Those burning in the hot air, however, dropped over 50 per cent. in strength after ten hours' burning, and burnt out at 40 hours.

The candle-power was not actually measured, but it was noticed that the lamps burning under the cold-flowing water did not lose in brilliancy after even a long period, while those at the room temperature did. The lamps running in the hot air lost considerably in brilliancy even during their 40-hour life.

The author gives rather a remarkable explanation of the behaviour observed. He ascribes the reduction in strength to the lowering of the vacuum as a result of the glass becoming porous when heated continuously. On the basis of these experiments, the author recommends that large metal-filament lamps should have no globes. In an ordinary clear-glass globe, with a 20 mm. diameter hole at the bottom, the temperature, after a run of 35 minutes, was found to be 70° C. With a matt or dusty globe much higher temperatures are reached, and the life of the lamp is shortened accordingly.

The author recommends the use of a small hood, as shown in the figure. A reflector, he holds, raises the temperature of the surrounding air, and is unnecessary, as little light is thrown by a metal-filament lamp in an upward direction. The absence of a reflector also enables the bulb to be cleaned by rain. The hood is of copper sheet 0·6 mm. thick, and the porcelain lamp socket is attached to a strong spiral spring, which presses the flange of the hood down on to the bulb, and prevents the lamp from becoming detached from the socket and falling out. Besides being conducive to long life, the design illustrated is put forward as being both cheap and pleasing to the eye.

The London B.T.-H. Team with the New Rugby Football.

## ELECTRICAL ENGINEERING IN THE MINING AND METAL INDUSTRIES

### STEEL REFINING IN AN INDUCTION FURNACE

A PAPER entitled "The Electric Refining of Steel in an Induction Furnace of Special Type" was read on Tuesday at the meeting of the Iron and Steel Institute in Brussels by Mr. Otto Frick. The Paper deals with the future development of the electric furnace, especially the induction furnace designed by the author. Two of these furnaces are at work in the Krupp works at Essen. The first came into regular operation in August, 1908, and the second, which was originally of the Kjellin type, has been rebuilt. Each is a 10-ton furnace and is used with good cold scrap. The actual working capacity is 8.5 tons and the weight of casts 6.5 tons. Each furnace is designed for 736 kw., but the average power used is 650 kw. The supply pressure is 5,000 volts single-phase and the frequency 5 cycles per second. The power factor at 8.5 tons is 0.53, and the average duration of one heat 6 hours 45 minutes. The theoretical power consumption per ton is given as 432 kw.-hours, so that the average losses are: electrical, 4.5 per cent., and radiation, 160 kw., giving an average total efficiency of 70 per cent. Figs. 1 and 2 give an idea of the design of these furnaces.

As previously mentioned, the Frick furnace is a modified Kjellin induction furnace. The iron being treated is contained in a crucible, formed round an iron core, which carries the primary winding, supplied with single- or two-phase current at a low frequency. The eddy-currents in the molten metal cause it to revolve. Returning to a consideration of the 10-ton furnaces, the original type with a rotating cover was chosen, as this allows of an even distribution of the cold scrap throughout the whole crucible, as well as facilitating supervision of the charge and of the furnace walls. Additions of slag and alloys are also easily made.

Comparing the properties of the Kjellin and Frick furnaces, the author deduces that the radiation losses are 48 per cent. greater in the former. On a run of six weeks, and with current at 0.43d. per unit, the cost of production per ton of metal, excluding interest and depreciation, is estimated at 41.1s. and 33.7s. respectively.

At the Krupp works a Girod furnace of 1,200 kw. and 12 tons capacity is also installed, and, comparing average results, the power required per ton of steel treated in the Girod furnace is about 1,000 kw.-hours, and in the Frick furnace about 600 kw.-hours. Assuming 7½ minutes between heats in the Frick, and 55 minutes and 1 hour 25 minutes in the Girod furnaces (these longer intervals being necessary for

FIG. 1.—10-TON 1,000 H.P. FRICK FURNACE.

charging, which has to be completed before the current can be switched on), the average losses are about 186 kw. and from 567 kw. to 594 kw. respectively, i.e., the loss in the Frick furnace is three times as little as the loss in the Girod furnace, although the capacity is only 20 per cent. less. It is also pointed out that the highest temperature attained in the Frick furnace is 1,680° C., while a maximum of over 2,500° C. is reached in the Girod furnace. The electrodes in the latter also serve to conduct the heat from the furnace, and the author concludes that in melting cold scrap the efficiency of an arc furnace cannot exceed 50 per cent., while in the Frick furnace it is over 70 per cent. The efficiency of a single-ring 20-ton furnace only varies from about 81 per cent. at 1,500° C. to 78.8 per cent. at 1,600° C.

Owing to the ring shape of the induction furnace crucible, difficulties are experienced with regard to cracking, while repairs cannot be so easily effected, as the walls are almost vertical. The lining developed by the author consists of magnesite of as high a quality as possible, and contains 93 per cent. of MgO without any binding agent. It is compact and strong and has no temperature coefficient. As all basic slags contain up to 10 per cent. of MgO, it is concluded that they saturate themselves up to this amount. Crushed magnesite of no use for other purposes is therefore introduced into the furnace so as to form a heap in front of the inner wall, against which it is pressed by the inclination and rotation of the bath. Fig. 3 shows a section through the lining and the bath, with its surface inclined towards the inner wall.

FIG. 2.—10-TON 1,000 H.P. FRICK FURNACE.

FIG. 3.—SECTION THROUGH LINING AND BATH.

The slag additions, mixed with magnesite, are shown as a heap M, and the rotation of the bath is indicated by an arrow. By this means the cutting of the lining has been prevented, as the silicon and phosphorus in the steel absorb the necessary amount of MgO and CaO before they reach the furnace wall. The linings so treated give a life of from two to three months regularly. As about two tons of metal are left in the furnace after tapping for the maintenance of the electric circuit, the magnesite has to be added immediately. The rotating cover of the furnace facilitates the distribution of the magnesite along the inner wall, the additions being fed along a small channel of sheet-iron at one of the openings during the rotation of the cover. It is found that the inclination of the bath surface is only between 4° and 5°, against 24° in the Kjellin furnace, so that the bath surface is kept economically covered with a minimum amount of slag.

Where furnaces are required for refining, as against melting from cold stock, special designs of doors for the quick handling of the extra slag are necessary. Tools are inserted through these doors to push the slag towards the spout and to prevent the formation of slag bridges. The doors are in the sides of single-ring furnaces and in the roof of double-ring furnaces. (A double-ring furnace is one in which the crucible is in the form of a figure eight, with one loop embracing each limb of the core.) The successes of the large furnaces in Essen has warranted the building of still larger types, up to 20 tons capacity, as single-ring furnaces; and double-ring furnaces up to 40 tons have been designed. All furnaces will preferably work with single-phase current, although the double-ring type may also be made to take a two- or three-phase current.

As induction furnaces have a very low power factor at the normal frequencies of 25 to 50 cycles, it is only in exceptional cases advisable to connect them directly to existing plants. It will in no case be economically justifiable to connect furnaces for steel of over 3 tons and for ferro-manganese of over 6 tons capacity to a supply system of 25 cycles, as the higher price of the furnace and extra power exceed the cost of the converting equipment. A double-ring single-phase furnace, compared with a two-phase furnace, shows that the extra cost of the iron core in the latter case is greater than the extra cost of the dynamo in the former. The induction furnace above two tons capacity is best suited to a frequency of between 5 and 15 cycles per second. Furnaces for melting ferro-manganese are smaller, and 25 or 50 cycles may be

used. The author has found that the apparent resistance of the furnace coils increases by about 7 to 7.5 per cent. for each cycle. The voltage may be anything up to 5,000. Comparing the costs of refining steel by the induction and arc furnaces respectively, the author's figures show that, allowing £50 per day for current, repairs, labour, interest and depreciation, the costs per ton are 4s. and 6s. 3d.; equivalent to a saving of £28 per day by the use of the induction furnace, not even taking into account the cost of the electrodes. The author looks to the electric furnace becoming chiefly used in combination with the Bessemer acid and basic processes. He thinks that the open-hearth furnace will soon disappear from those districts where ores suitable for acid or basic working are found, as the costs vary between 6s. and 12s. per ton for the production of Bessemer steel, and between 5s. and 8s., or possibly 10s., per ton for electric steel produced in the induction furnace. For the melting of ferro-manganese the melting costs vary between 20s. and 30s. per ton, or between 10 and 15 per cent. of the value of the FeMn. By pre-melting the FeMn in the electric furnace, not only an improvement of the quality of the steel, but also a saving in cost, may be gained, varying between 5 and 30 per cent. of the value of FeMn, say 10s. to 60s. per ton of FeMn.

A considerable portion of the Paper is given over to a consideration of metallurgical reactions, and the opinion that a thin and liquid slag is unnecessary in the induction furnace is upheld. Particulars of the following reactions, which may be readily carried out, are also given:—Decarburisation, desiliconising, dephosphorisation, deoxidation, rephosphorisation, desulphurisation, recarbonising, and alloying with silicon, manganese, nickel, chromium, tungsten, etc. In the latter case the gentle rotation of the bath ensures a perfect distribution. Deoxidation by the old method with ferro-silicon is considered to be the most satisfactory in the induction furnace. During the process of desulphurisation it is shown to be bad economy to try to produce calcium carbide in the steel furnace.

## REPORTS OF DISTRICT INSPECTORS OF MINES

IN accordance with our usual custom, we give below a *résumé* of the published reports for 1912 of the various District Inspectors of Mines in so far as they relate to the use of electricity. It will be noticed that satisfactory increases are shown in the number of electric safety lamps in use, as well as in the number of electrically-driven coal-cutting machines. The decrease in the number of accidents due to electricity is also satisfactory. There was, however, an explosion due to the sparking of a signalling bell at Bedwas Colliery (South Wales district). The bell was carried too near to the coal face.

### Scotland District

Mr. W. Walker reports that there has been an increase since 1911 of 92 electrically-driven coal-cutting machines, and an increase of three driven by compressed air. The total number of machines in use at the end of the year was: compressed air, 178; electric, 595. Of the latter 392 were disc type, 177 bar, 12 chain, 9 percussive, and 3 rotary heading.

There were 282 electric safety lamps in use, compared with 155 in 1911. Of these 127 were Sussman-Gray, 94 C.E.A.G., 45 Float, and 16 various. The total number of safety lamps (both oil and electric) in use was 34,758, compared with 35,098 in 1911. Of these 9,146 were magnetically locked, compared with 7,924 in 1911, while 10,710 were ignited by electricity, compared with 8,592 in 1911.

The aggregate horse-power in motors installed on the surface was: Winding, 1,666; ventilation, 2,363½; haulage, 2,527; coal-washing or screening, 5,515; miscellaneous, 6,944½; for underground working the figures are: haulage, 22,813½; pumping, 36,143½; portable machinery, 17,367; miscellaneous, 3,018½. Thus the totals are 19,014 and 79,343 respectively.

The report states that one person was killed by electric shock, and nine were injured. Mr. Walker remarks that this is a record for the Scotland district, and is very satisfactory in view of the large amount of electric machinery in use. The result, he says, is "to some extent due to the good work which is being done by the Association of Mining Electrical Engineers in Scotland, and which has resulted in a better class of colliery electricians being employed at the majority of the mines, with the result that the supervision is more careful than was the case in former years."

The fatal accident was due to a coal-cutting machine in a wet situation being badly earthed. Three-phase current at 440 volts was used. Mr. R. Nelson (Electrical Inspector of Mines), found that the earth-wire at the surface was fastened to a short length of rusty rail buried some 3 ft. in the ground. The earth cable was so slack that some earth had forced itself between the head of the bolt and the web of the rail. There was also an intermediate earth plate dipping into water in a sump, whereas the Special Rules state that earth plates should be sunk in the ground. Of the non-fatal accidents, three were due to abrasion

of the insulation of unarmoured cables, three of failure of the insulation of trailing cables, while the remainder were due to "casual and careless methods of working." In connection with Section 32 of the Coal Mines Act, which requires that the whole of a seam, in which an explosion of inflammable gas occurs causing any personal injuries, must be worked with safety lamps, Mr. Walker writes: "The use of safety lamps at present is not popular, either with owners or the persons employed, and every possible argument is used against their use, and, in particular, that other classes of accidents will be increased. Having had considerable experience in this and other coal fields, I do not agree. . . . With portable electric lamps a better light is obtained than is obtained with a naked light. It is often urged that the weight of the electric safety lamps is excessive, but I would point out that this should not prevent their being used, as it is probable experience gained from practical use will remedy this defect." An explosion occurred while some gas was being "bottled up," probably by an oil safety lamp being knocked over, and Mr. Walker says: "The stopping was eventually completed by firemen using electric portable lamps. If this precaution had been adopted at first, the accident probably would not have occurred." There were two prosecutions of miners for contravention of the electricity special rules.

### Newcastle District

According to Mr. J. B. Atkinson's report there has been an increase since 1911 of five electrically-driven coal-cutting machines, and an increase of 40 driven by compressed air. The total number of machines in use at the end of the year was: compressed air, 304; electric, 51. Of the latter 24 were disc type, 12 bar, 14 chain, and one rotary heading.

There were 1,522 electric safety lamps in use, compared with 871 in 1911. Of these 1,487 were Sussman-Gray, 15 Oldham, 12 Mecco, and eight various. The total number of safety lamps in use was 61,841, compared with 61,864 in 1911. Of these, 22,187 were magnetically locked, compared with 21,143 in 1911, while 25,594 were ignited by electricity as against 24,107 in 1911.

The aggregate horse-power in motors installed on the surface was: winding, 3,159; ventilation, 4,402½; haulage, 2,333; coal-washing or screening, 3,318; miscellaneous, 5,511; for underground working the figures are: haulage, 11,361½; pumping, 13,128½; portable machinery, 1,627½; miscellaneous, 2,309½. Thus the totals are 18,723½ and 28,427 respectively.

There were three fatal accidents, resulting in three deaths, attributed to electricity, and two non-fatal, in which two persons were injured. One of the fatal accidents was due to an electrician not knowing that a switch was alive, another was due to a metallic casing on a coal conveyor switch not being earthed (the mine manager was prosecuted but not convicted), and the third was due to a haulage motor starter having an exposed live part. The pressure was 450 volts D.C.

### Durham District

Mr. A. D. Nicholson reports an increase of four electrically-driven coal-cutting machines, and seven driven by compressed air. The total number of machines in use at the end of the year was: compressed air, 90; electric, 59. Of the latter 23 were disc type, 20 bar, 14 chain, and 2 percussive. The report continues: "A start has been made in the district to use machines driven by low pressure electricity of 220 volts, and the method adopted is now working very well at Messrs. Bolckow, Vaughan & Co.'s collieries. I trust that in time the use of higher pressures for coal-cutting machines will give place to low pressure, as the risk from shock is thereby reduced to a minimum."

There were 3,573 electric safety lamps in use, compared with 2,075 in 1911. Of these 3,543 were Sussman-Gray, 15 Oldham, and 15 various. The total number of safety lamps in use was 67,351, compared with 64,146 in 1911. Of these 30,745 were magnetically locked, while 37,826 were lighted by electricity, compared with 34,731 in the preceding year.

The aggregate horse-power in motors installed on the surface was: winding, 2,149; ventilation, 6,224; haulage, 3,748; coal-washing or screening, 6,080; miscellaneous, 9,409; for underground working the figures are: haulage, 15,918; pumping, 17,988; portable machinery, 1,550; miscellaneous, 700. Thus the totals are 27,610 and 36,156 respectively.

One fatal accident occurred underground on a 250 volt A.C. lighting circuit. Part of the wire was bare, but it was over 6 ft. from the floor. There was one fatal accident on the surface, also on a 250 volt circuit, and this accident "would not have happened if ordinary precautions had been observed by the deceased."

### Manchester and Ireland District

Mr. J. Gerrard's report shows an increase of two electrically-driven coal-cutting machines, and 19 driven by compressed air. The total number of machines in use at the end of the year was 150 compressed air and nine electric. Of the latter six were of the bar-pick-quick type, and two of Hopkinson chain type.

There were 373 electric safety lamps in use, compared with 103 the previous year. The total number of safety lamps in use was 46,945, compared with 46,221. Of this number 5,411 were magnetically locked, compared with 5,167 in 1911, and 9,247 were ignited by electricity, as compared with 9,133.

The aggregate horse-power in motors installed on the surface was: winding, 110; ventilation, 830; haulage, 246; coal-washing or screening, 1,167; miscellaneous, 2,052½; for underground working the figures are: haulage, 2,666; pumping, 3,097½; portable machinery, 234; miscellaneous, 437. Thus the totals are 4,405½ and 6,434½ respectively.

No accidents due to electricity are reported.

#### Liverpool and North Wales District

Mr. J. R. R. Wilson reports an increase of seven electrically-driven coal-cutting machines, and three driven by compressed air. The total number of machines in use was: compressed air, 124; electric, 24. Of the latter 12 were bar type, seven disc, four chain, and one percussive.

There were 204 electric safety lamps in use, compared with 188 in 1911. Of these 167 were Sussman, 18 Oldham, eight C.E.A.G., while the remainder were of various other makes. The total number of safety lamps in use was 66,817, as against 65,472. Of these 21,325 were ignited by electricity, and 10,258 were magnetically locked. In 1911 the numbers were 21,074 and 10,579.

The aggregate horse-power in motors installed on the surface was: winding, 25; ventilation, 1,111½; haulage, 255; coal-washing or screening, 1,304; miscellaneous, 1,309; for underground working the figures are: haulage, 5,686; pumping, 4,132; portable machinery, 409; miscellaneous, 820½. Thus the totals are 4,04½ and 11,048 respectively.

No accidents in coal mines due to electricity are reported.

#### South Wales District

Dr. W. N. Atkinson reports that the number of electrically-driven coal-cutting machines has increased by seven since 1911, while the number of compressed air machines has decreased by six. The total number of machines in use was: compressed air, 64; electric, 50. Of the latter 37 were of the bar type, seven disc, four chain, and two percussive.

There were 71 electric safety lamps (20 were of the Float type) in use, compared with six the previous year. The total number of safety lamps in use was 183,985, compared with 177,517. Of this number 104,685 were ignited by electricity, compared with 105,336, and 88,443 were magnetically locked, compared with 81,690.

The aggregate horse-power in motors installed on the surface was: winding, 16,129½; ventilation, 11,299½; haulage, 11,696; coal-washing or screening, 7,075½; miscellaneous, 24,711½; for underground working the figures are: haulage, 32,733½; pumping, 45,638½; portable machinery, 926; miscellaneous, 1,183½. Thus the totals are 70,911½ and 78,481½ respectively.

Ten non-fatal accidents due to electricity were reported, as well as one fatal accident on the surface. The earthing of the cable in the latter case was defective. An explosion of fire-damp was also caused by the sparking of a signalling bell. Dr. Atkinson states: "No great force was developed by the explosion, but indications of flame could be traced for a distance of about 70 yards along the level; 20 yards in-by, and 50 yards out-by from the electric bell. The level was rather damp, and was practically free from coal-dust. The electric bell of trembler type was worked by an induction coil, and a battery of eight Leclanche cells placed near the bell. The battery produced current at 11½ volts pressure when tested after the accident. It was afterwards proved experimentally, that sparks from this bell when rung by a current at 11½ volts would ignite an explosive mixture of lighting gas and air; and the mixture was also fired by sparks from signalling wires produced by a current of only four volts pressure. I believe this explosion at Bedwas Colliery to be the first recorded case of a colliery explosion caused by sparks from signalling apparatus, and it is curious that another (non-fatal) explosion due to the same cause, occurred at another colliery later in the year. It has become the practice recently to carry the electric signals nearer to the working faces than was formerly done, this increasing the probability of fire-damp coming in contact with the bells or wires. The new electrical special rule, No. 15, requiring extra precautions where gas is likely to occur, partly meets the danger, and should be strictly observed in fiery mines."

Some mystery also surrounds an explosion in a shaft at Mark ham Colliery, though it is thought that it was probably due to the cable for connecting a lighting battery with a lamp cluster being fitted with a simple three-pin plug and socket. Two accidents due to the premature explosion of electric blasting fuses were also reported.

### THE CRYSTALLISING PROPERTIES OF ELECTRO-DEPOSITED IRON

A PAPER with this title was read at the Brussels meeting of the Iron and Steel Institute on Tuesday, by Dr. J. E. Stead and Dr. H. C. H. Carpenter. As the result of extensive tests, the authors find that electro-deposited iron sheet of a high degree of purity—over 99.95 per cent. of pure iron—exhibit remarkable recrystallisation effects when heated rapidly to a certain temperature and then rapidly cooled. The coarse crystals so produced are sometimes "equi-axed" and some-

CO., LD  
DAGENHAM DOCK,  
ESSEX.**

times "radial." Frequently both types occur on the same specimen. There is no reason for thinking that they are constitutionally different, and they are most probably  $\alpha$ -iron. These crystallisation effects are only obtained when the thickness of the iron sheet or strip does not exceed a certain critical figure, which is between 0.011 and 0.012 inch. The most striking results are produced at a thickness of 0.009 to 0.01 inch. These coarse crystals cannot be destroyed except either by cold mechanical work, or by heating and quenching at certain temperatures, and the results give no support to the view that there is any crystallographic difference between  $\beta$  and  $\alpha$  iron. It is interesting to note that the very heat treatment that produces coarse crystals in the electro-deposited irons refines wrought iron and very mild steel that have been rendered coarsely crystalline by "close-annealing" between 700° and 800° C. On the other hand, annealing at 700° to 800° C. has no effect in coarsening the structure of the electro-deposited iron which has been refined by cold mechanical work. The authors' view is that the recrystallisation phenomena of the pure electro-deposited iron can be most satisfactorily explained on the assumption that the iron changes direct from the  $\gamma$  to the  $\alpha$  condition.

**Contravention of Home Office Electrical Mining Regulations.**—On Saturday, August 9th, before the Ashby-de-la-Zouch (Leicestershire) Petty Sessions, 18 summonses for continued neglect of the Home Office special rules for the use of electricity in mines were preferred by the Home Office against the Measham Collieries, Ltd., and also against Mr. T. Watson, who was at the time the mine manager, but who now holds a similar position at Wigan. Of the alleged offences, nine were for failing to earth switch and junction boxes, five were for unscreened fuses, two for cables from which the insulation had been torn off, and two for not providing buffers to prevent abrasion of the insulation. Mr. Watson contended that he was not liable, as he had been hampered by not being allowed to order what was necessary to remedy the defects, which he had brought to the notice of the director, Mr. R. D. Waddell, who in turn denied that there was any restriction on Mr. Watson's expenditure except as to new plant. He had told Mr. Watson to get the equipment in order. The Bench decided to acquit Mr. Watson, but convicted the Colliery Company on all the summonses. They imposed a fine of £105 and £19 4s. costs.

## ELECTRIC MINING AND METALLURGICAL PATENTS OF AUGUST

THE following patent specifications, published during August, are of particular interest to mining electrical engineers. No. 14,385, of 1912, by J. L. Hudson (Newcastle-on-Tyne), describes a locking device for miners' electric safety lamps, in which the upper end of a bolt engages a socket in a cap screwed to the upper end of the casing, and traverses a tube inside the casing. The bolt is in contact with a guard in a lower cover, screwed on to a gallery below the casing, and pressed upward by a spring on to the bolt. On the withdrawal of the guard by a magnet, the bolt falls by gravity out of the socket in the cap. Thus the cap and lower cover are unlocked from the casing. No. 14,547 of 1912, by A. Paxton (Cardiff), deals with the electric lighting of oil safety lamps, and covers a construction of lighting generator in an independent flame- and gas-proof case, combined with a switch and key. The actual ignition device is contained in the safety lamp, and there is a locking arrangement which prevents the switch from being closed, unless the lamp is properly connected up to the generator.

A method of signalling between a mine cage or skip and the mouth of the shaft is described in specification No. 4,256 of 1913, by G. A. Loudon (London). The haulage cable has formed with it, or serves as, the conducting line, and, connected with it on the winding drum, is the signalling bell. In specification No. 16,441 of 1912, G. Kahler and F. Junker (Germany) describe how the spread of fires and explosions may be stopped by the automatic action of water-sprinklers on the products of combustion after a blasting charge is fired. The sprinklers are put into operation through an electro-magnet in the firing circuit, and also by an independent mechanism worked by the wave of air preceding the gases. In specification No. 20,560 of 1912, by W. E. Lake, as communicated by the Fabrik Elektrischer Zunder, of Germany, an improved machine for preparing the conducting wires of blasting fuses, in which the wires are drawn off reels

and are wound by an arm several times consecutively round two or more pins, is claimed.

The specifications of special interest to electro-metallurgists include No. 25,974 of 1912, by P. L. T. Héroult (U.S.A.), in which a process for making high grade pig iron from phosphorus ores is described. The liquid iron is treated in an electric furnace, at a low temperature in a non-oxidising atmosphere, with a basic slag containing much limestone and a little iron oxide, so that the slag combines with the phosphorus without altering the carbon content. To eliminate sulphur, the first slag may be removed, and a highly basic slag free from iron oxide introduced.

In specification No. 4,595 of 1913 a magnetic separator is described by the Friedr. Krupp Aktiengesellschaft Grusonwerk. The magnet poles rotate within a stationary ring-shaped armature, while the material to be treated is conveyed through channels rotating with the magnet poles.

**Colliery Fatality.**—On the night of August 15th two men, named E. Clarke and E. Spaulton, lost their lives at the Moor Green Pit, belonging to Barber, Walker & Co., of Nottingham, owing to an accident to a coal-cutter which they were driving. It appears that it could not be properly run up to full speed, and the deceased sent a third man to find the electrician in charge, who, on his arrival, found that both men had in the interval been killed by shock, while one had also come in contact with the cutter wheel. The inquest was opened on August 18th, but was adjourned for the Home Office to be represented. The Notts Miners' Association desired that a thorough examination of the scene of the accident should be made by two competent workmen. At the adjourned inquest Mr. L. G. F. Routledge (chief electrician to the colliery company), said that on the day following the accident, on opening the box containing the motor, he found a broken stator barrel contact in the controller, and a burned out earth connection on the pummel. To these he attributed the accident and the death of the two men. Inspections were made weekly, but were not reported unless a defect was found. Mr. R. Nelson (Electrical Inspector of Mines) attached no blame to anybody, but he thought a report should be made when machines were found to be in order as well as when they were found to be defective.

## "ALDRA" Fire-Proof Insulated Aluminium Wire

For the manufacture of coils for **continuous and alternating current** of any voltage. Our aluminium wires with inorganic insulation are distinguished by their **fireproof quality**, so that a coil can be subjected to temperatures up to 500° C. without damage.

The insulation **resists chemical action**.

The insulation has a **high dielectric strength**, so that there can be a maximum pressure of about 500 volts between two adjacent wires.

**Excellent space-factor** almost equal to that of bare wire.

**Large saving in weight and price** compared with copper coils.

## THE MAZDA "HALF-WATT" LAMP

AS mentioned in our last issue, the British Thomson-Houston Co., Ltd., exhibited specimens of their new half-watt lamp to representatives of the Press last week. In making the announcement, Mr. F. W. Willcox said:—

GENTLEMEN: On behalf of the British Thomson-Houston Company I have the pleasure of welcoming you to-day and presenting you with some information regarding an important and far-reaching development in electric lighting—the new Mazda half-watt lamp. It is the privilege of the British Thomson-Houston Company, through their associates in America—the General Electric Company of New York, to be closely identified with this important development, and this meeting has been arranged in order that we may rightfully place the credit for this invention where it belongs, and establish the position of the Mazda lamp and the British Thomson-Houston Company with reference to it.

I may be pardoned for reminding you that it was just two years ago this time that we had the privilege of meeting you and other Press representatives at Rugby on the occasion of a previous important lighting development. This you will remember was the drawn-wire tungsten filament, first developed with and supplied in the Mazda lamp. The developments since that time have fully justified the claims then made for the drawn-wire filament, which has greatly improved the strength and durability, and promoted a much wider application and use of the tungsten filament lamp.

Marked progress has been made in the advancement of the quality of the drawn-wire Mazda lamp. As now manufactured, the drawn-wire lamp is much more rugged in construction, and, with greatly improved efficiencies, yet gives actually longer service than the lamps at lower efficiencies formerly made. As a result of the improvements in efficiencies, the user has been continually receiving lamps that produce more light for the same power consumption and cost. It is not too much to say that Mazda lamps have advanced more in efficiency in five years than carbon filament lamps have advanced in twenty years. These improvements have been made only as a result of improved methods of manufacture, and have not been made at the expense of the life of the lamps, which has not suffered by such changes. The drawn-wire filament has also permitted lamps to be made with much greater accuracy as regards voltage, candle-power, and current rating.

The British Thomson-Houston Company and their associates in America are in the fortunate position of having the most extensive lamp manufacturing facilities in the world, supported by a tremendous volume of lamp business, and backed by a fund of experience and technical knowledge that is unequalled. Both on this and on the other side of the Atlantic there are at present some 15 lamp factories at work producing more than a million Mazda lamps a week. As is well known, all the Mazda lamps for the British market are British made at our lamp works at Rugby.

An organisation of such magnitude, as this can afford, and the policy has been, to expend regularly large sums of money in scientific research and investigation, and in the purchase of new equipment and plant for the production of the latest improved lamps. This policy of scientific research and lamp development work has been steadily, constantly, and persistently pursued for a period of years, and the development we show you to-day is the latest result of this far-seeing policy. It is no haphazard result or sudden discovery, but is the product of some years of persistent research and development.

This research and development work is carried on in a number of electrical laboratories owned by the associates of the British Thomson-Houston Company. In these laboratories a staff of more than 50 research experts, and as many more technically trained assistants, are constantly working to make Mazda lamps better and cheaper. The principal laboratory is located at Schenectady, New York, and it was at this laboratory, under the direction of Dr. W. R. Whitney, that the new half-watt Mazda lamp has been developed. Although announcements of the half-watt lamps have already appeared from the Continent, and in this country, we have made this an occasion for the purpose of recording the fact that the invention of this lamp is the result of a most carefully planned series of investigations, carried out during the past two years by the research laboratory of the British Thomson-Houston Company's associates in America—the General Electric Company of New York.

The lamps we are to show you to-day have been manufactured at our lamp works at Rugby, under the patent rights which the British Thomson-Houston Company is entitled to from their American associates. Although these lamps evidence the fact that the invention is past the experimental stage, it will require some time yet before they can be placed in regular production for the British market.

The first lamps to be supplied will be of high candle-power sizes, running from about 300 to as high as 1,500 candle-power or more. The efficiency of the lamps to be shown you to-day will average about half a watt per candle on the British standard

candle-power basis, and the useful light at this efficiency will run as high as 1,000 hours.

The lamp is substantially the same in general construction as the ordinary incandescent lamp, the chief points of difference being the form of the filament (which is drawn-wire tungsten), and the employment of a gas-filled bulb.

Four lamps were exhibited, with the following amperage (at 80 volts), candle-powers, and efficiencies:—

No.	Amperes (at 80 volts)	British Standard Candle Power.	Watts per British Standard Candle Power.
1	9.2	1,400	0.52
2	9.15	1,375	0.53
3	9.1	1,260	0.535
4	10.0	1,600	0.50

One of these lamps is illustrated below. The shape of the filament differs from that of the present

1,600 c.p. MAZDA LAMP.

(10 amperes at 80 volts = 0.5 watts per candle.)

metal filament lamps, being a closely-wound helix, the close turns of which, however, are not perceptible on the photograph or when the lamp is lighted. The bulb is stated to be filled with an inert gas, such as nitrogen, and we are informed that it is the action of this gas which enables the enormous efficiency of illumination to be obtained. Reasons connected with the filing of patents render it undesirable to enter into further details at present, but we hope on some future date to be able to present our readers with more particulars.

Another interesting exhibit was one of the earliest experimental half-watt lamps made at the laboratory of the General Electric Co., Schenectady, New York. This was a 25-volt lamp, taking 20 amperes, and giving 1,200 c.p. at 0.4 watts per candle.

**A New Publication.**—A book by Mr. W. Perren Maycock, entitled "Electric Circuit Theory and Calculations," will be published at the end of the month by Whittaker & Co. The properties of the electric current are dealt with, and machinery, distribution, and illumination problems are touched on. A section is devoted to the principles of arithmetic. The book is especially intended for contractors, wiremen, and students.

**American Water-Powers.**—The Canadian Conservation Commission has condemned the projected scheme to dam the St. Lawrence River, at Long Sault Rapids, in a recent report. According to *The Times* a charter had been obtained from the New York State, but not from the Canadian Government. The damming of the river would be contrary to the Ashburton Treaty of 1845, says the report, as this provides that the channels shall be free and open to Great Britain and the United States and no constructions which might interfere with navigation can be erected without the consent of Great Britain.

### A NEW PIPE CLIP

**I**N first class surface wiring work it is frequently necessary (especially in hospitals and similar institutions) to carry the pipe containing the wires a short distance from the wall. Among the latest clips for this purpose which has been brought to our notice, is one manufactured by Smith & Davis (Beacon Works, Hampton Street, Birmingham), which we illustrate. As will be seen, it can be fixed to be used for either horizontal or vertical runs, and also for ceiling work. The bolt and nut fastening enables it to adjust itself automatically and to allow for slight variations in the thickness of the pipe. The clip is made of heavy gauge sheet-metal and its price is moderate.

### THE "KARTRET" INDICATING FUSE

**W**E recently had an opportunity of inspecting an ingenious indicating fuse made by the Kartret Engineering Co. (for which firm Messrs. Nathan & Allen, of Queen Anne's Chambers, Westminster, are selling agents). Both the fuse holder itself and the indicating device are extremely ingenious, and, as they are strong and well-made, they should be extremely popular. Fig. 1 shows a plain "Kartret" fuse holder, without indicating device, and the construction of the terminals (in which no screwing down of the fuse wire is required) is also seen in Fig. 2. The fuse-wire is simply threaded through the holder and the shutters at the end—shown, both open in Fig. 1, and one closed and one open in Fig. 2—bend the wire down over the

FIG. 1.—"KARTRET" FUSE HOLDER WITHOUT INDICATING DEVICE.

terminal blocks and hold it securely. The shutters are slightly curved, so that, when pressed down through the clips which hold them, they are very secure, and neither ordinary vibration nor A.-C. currents will work them loose. Both

SECTION OF INDICATING FUSE HOLDER,  $\frac{1}{2}$  SCALE. END ELEVATION, SHOWING SHUTTER OPEN AND CLOSED.

Fig. 2.

the shutters and the clips are of phosphor-bronze, so that they are elastic and retain their shape.

In the indicating fuse-holder shown in Fig. 2, a loose plunger of insulating material passes through a hole in the

centre of the porcelain bridge, and, when no fuse is in, it is pressed above the level of the top of the porcelain by a weak helical spring. To insert the fuse, the plunger is pressed down and the fuse threaded through a hole in it, and the two ends of the fuse wire are gripped by closing the shutter fastenings as in the ordinary fuse. The fuse wire then holds down the plunger, which rises, however, to the position shown in the dotted lines as soon as the fuse blows. An incidental advantage is that the fuse that has blown can be found in the dark by passing the hand over the row of fuse-holders and feeling for the projecting button.

### A NEW DESIGN OF SUCTION CLEANER

**A** CONVENIENTLY arranged suction cleaner for ordinary household work has been introduced by Simplex Conduits, Ltd. (116 Charing Cross Road, W.C.) at the low price of £6 10s. The machine, which is of the broom-handle type, is only 8 lbs. in weight, and is provided with a "pistol grip" handle and control switch. The overall height is very small, enabling the apparatus to be used in intricate corners, &c.

FIG. 1.

FIG. 2.

FIG. 3.

DESIGN OF NOZZLES.

The suction is produced by a quiet motor-driven high-speed fan. A new design of nozzle giving a large actual working area, is provided; this is shown in Fig. 1. It is lozenge-shaped so as to penetrate into difficult positions, and is said to give a minimum of wear and tear on the carpets. For cleaning hard wood, linoleum, &c., the nozzle shown in Fig. 2 is used. It is seen that the slot through which the dirt is drawn always precedes the felt pad necessary to give the suction effect. The dust bag is easily removed, and replaced on the handle by a simple spring clip, while the various nozzles are easily detachable, as shown in Fig. 3. Besides this machine, known as the "Diamond," a more powerful machine, called the "Diamond Special," using  $\frac{1}{2}$  h.p. and intended for larger establishments, has been designed. The motor runs at nearly 8,000 r.p.m. Demonstrations are given at the Simplex Company's branches, and neat overprinted booklets can be had on application by contractors and other retail houses.

**Industrial Lighting.**—This is the title of a new illustrated book of 22 pages, dealing with the important question of efficient mill and factory lighting, which is published by the British Thomson-Houston Co., Ltd. (Mazda House, 77 Upper Thames Street, E.C.). The book should prove of great benefit to owners and managers, as the subject is presented clearly and logically. It is first shown why good lighting is necessary, then, the results which accrue from improved lighting, and thirdly, how good lighting may be obtained. The book contains a number of illustrations of mills and factories which have been lighted in an up-to-date and scientific manner by the British Thomson-Houston Company. One important advantage of improved lighting is indicated in the statement that "experts give 1 per cent. as the average gross spoilage in our total manufactures, an item, in the year 1907, of approximately £12,560,000. Of this large amount of spoilage 75 per cent. is estimated to have occurred under artificial light, and expert opinion indicates that 25 per cent., or £2,355,000 of this, could have been avoided by good illumination." Two charts, which tell graphically the story of the loss which results from inadequate light are given. In one is shown the average ratio between darkness, cloudiness, and sunlight. In the other is set forth the "curve" of fatal industrial accidents in three successive years, as reported from 80,000 industrial plants. These charts show that fatal accidents increase during the dark periods of the year, and decrease as the days get longer. It will be appreciated from this that good illumination is an important factor in the prevention of accidents. As most of our readers are aware, the Company has organised an illuminating engineering department, equipped with modern facilities and appliances for the design and testing of lighting apparatus and the preparation of installation schemes.

# QUESTIONS AND ANSWERS BY PRACTICAL MEN

## RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

## QUESTION No. 1,354.

WHAT are the advantages gained by the adoption of electrical over steam driving for sheet rolling mills, and are there also any disadvantages? If possible, state the saving derived per ton of sheets rolled by electrical driving compared with steam driving.—"MORGAN MORGAN."

(Replies must be received not later than first post, Sept. 11th.)

## ANSWERS TO No. 1,352.

I HAVE recently become responsible for laying air space telegraph and telephone cables, and should be glad to have some information on the following points:—(1) Is desiccating apparatus absolutely necessary? (2) Give a design for a really accessible test box having high insulation, for use in railway signal boxes. (3) What is a satisfactory way of securing a lead-covered cable when it has to be carried straight up a wall? (4) Is any harm likely to accrue if a 4-in. sag is allowed in an armoured cable supported on hooks 6 ft. apart? (5) What is a satisfactory form of lightning protector?—"POTHEAD."

The first prize (10s.) has been awarded to "E. M. F." for the following reply:—

(1) With very dry climate, faultless cable jointing, and perfectly reliable workmen, one can manage without desiccating apparatus; but as all these stipulations can never be guaranteed in practical work, "Pothead" will do well to provide himself with at least a hand desiccator—or with a petrol-driven one, if the cable system is at all extensive—in order that low insulations may be quickly corrected.

(2) Accessibility and high insulation are two conditions not easily complied with in test-boxes, to be placed in positions where damp air may have access, and it may be found advisable to instal two types of box. Fig. 1 shows a type suitable for large signal boxes, where the conditions are good, and where trouble may not be anticipated from a

FIG. 1.

FIG. 2.

deposit of moisture on the slate panel. The circuits terminate on metal plug holes, and U links are employed for permanent connections. For temporary cross connections, earthing, testing, &c., a special pair of plugs is used. The

lower half of the box is used for tagging up the "inside" cables. In damp low-lying country a box of the type shown in Fig. 2 will be found necessary for maintaining high insulation. In this case the circuits terminate on jacks supported in an air-tight space behind the front ebonite panel. The connections are obtained by inserting plugs in the jacks through holes in the front panel. The connections are shown for a double wire telephone circuit, and for a single wire telegraph or signalling circuit. It will be seen that, in this type, the circuits are "through" for normal working, with no plugs inserted, and the stopping up of all the plug holes in the panel with dummy plugs allows of the interior being kept very dry. As a safeguard a saucer of chloride of lime should be kept inside the case and renewed when it becomes moist.

(3) For light cables up to about an inch diameter, simple wooden cleats, Fig. 3, secured by long coach screws to wall plugs, will be found to be all that is necessary. For heavier cables, light rag bolts, carrying a wooden bearer and iron clamp, form an excellent fixing. In both cases it should be borne in mind that with air space cable it is not sufficient to support the weight of the lead cover only. The conductors

FIG. 3.

FIG. 4.

must also be well gripped, and for this purpose short lengths of split wrought-iron piping can with advantage be inserted inside the clamp to surround the cable.

(4) No harm is likely to accrue with this sag, if the supporting hooks are fitted with broad bearers, having a curved upper surface and rounded edges. Sharp edges at the supports should be avoided.

(5) The best form of lightning-protector is the vacuum serrated type, in which two blocks of carbon, having opposing furrowed surfaces, are carried inside a glass tube containing a vacuum, and fitted with metallic end plates for making connection to the circuit on a protector frame. A cheaper form, and one which is reasonably satisfactory, consists of two carbon blocks laid together with a thin sheet of mica between, the mica being punched with one or more small holes. One block is earthed, and the other joined to the line by insertion of the pair into a spring clip carried in the frame. This type is illustrated in Fig. 4.

With regard to (1), it may be mentioned that, in the early days, many dry-core cables were laid and used before drying-out by pumping dry air through the cable became the usual practice. Every precaution was taken by the jointers to keep the paper dry during jointing, and the joints were heated in dry unslaked lime before the lead sleeve was drawn over and soldered. Of course, the lead joint had to be perfect, and the endboxes or pot-heads had also to be moisture-tight. For short lengths of dry-core cable, desiccating apparatus is not essential. "E. M. F.'s" test-boxes described in (2) might with advantage be supplemented in damp places by pot-heads at the end of the dry-core cables, from which rubber tails would be brought to the test-box. With regard to (5), it may be added that several good lightning-protectors are on the market, and that it would be unnecessary to use a home-made one.

No reply of sufficient merit has been received to enable us to make a second award.

With regard to the answers to Question No. 1551, published in our last issue, W. R. J. (who was not a competitor) writes us that while he agrees to a certain extent with the views expressed in the two answers selected for awards, he wishes to point out that in Leeds alone there are a number of makers of single-phase motors who would be prepared to guarantee efficiencies comparing quite favourably with D.C. motors. Where

constant speed is not objected to, and means could be taken to ensure starting against light loads, he contends that this type of motor would be at least as, if not more, satisfactory than a D.C. motor. "As regards variation of speed," he continues, "there are now on the market quite a number of lines of motors, with characteristics in every way similar to those of a shunt-wound interpole D.C. motor. I may mention, for instance, the machine built by Messrs. F. Parkinson & Co., Leeds, under Punga-Creedy patents, wherein a speed variation by shunt control of 3 to 1 can be obtained, and that with an efficiency of a fairly high value. As regards the power factor, this, as a rule, only interests the supply company, and it is not worth the consumer's while to go to great expense to avoid low power factor." His particular objection to the use of a motor-generator for the case in question, is its losses at light load. W. R. J. writes well, and we hope that he will now enter the lists frequently on our Questions and Answers page, but not, as in this instance, merely as a correspondent *ex post facto*.

## THE MISSISSIPPI HYDRO-ELECTRIC SCHEME

### 2. High Pressure Switchgear, Transmission Lines, and Sub-stations at St. Louis

WE now supplement the general description of the large generating station at Keokuk, on the Mississippi, which appeared in *ELECTRICAL ENGINEERING* for August 14th on p. 467, by some particulars of the transmission system and the large sub-station at the end of the line at St. Louis.

The main transmission line extends to St. Louis, a distance of about 144 miles, while the towns of Hannibal, Quincy, Fort Madison, and Burlington are on the route. The line consists of heavy twin circuits carried in parallel vertical planes on a single set of steel towers. The conductors are of copper, 300,000 circular mils section. Each cable consists of 19 strands of hard-drawn copper, giving an overall diameter of 0.625 in. The spans are about 800 ft., so that it is calculated that there is ample margin in strength, as the ultimate strength is 14,000 lbs., while with a half-inch ice coating in a 60-mile gale at 0° F. the loading would be about 7,000 lbs. The corona point is 148,000 volts. The steel towers used on the straight sections are 79 ft. high with a 20-ft. square base. They weigh 3½ tons, and each leg is bolted to a reinforced concrete foundation weighing 2 tons extending 6 ft. down. Every tenth tower, as well as those at railway and river crossings, &c., is an anchor tower. These are 4 ft. high, with bases 24 ft. square, and weigh 5 tons. They are set on four concrete foundation legs, extending 8 ft. down, and each leg weighs 7½ tons. They are designed for a dead-end side pull of 50,000 lbs. In addition to the six main conductors, which are arranged in two vertical planes and are suspended from 7-part insulators tested up to 440,000 volts dry and 330,000 volts wet, an earth wire of 0.5 in. galvanised Siemens-Martin steel is carried on the peaks of the structures. To prevent the crushing of the separate strands of the copper lines, a special open-hearth steel clamp with a waved groove was devised. At anchor towers all the conductors are dead-ended through eight disc strings of insulators. The span across the Mississippi where the line leaves the power-house is 2,800 ft. in length and is supported by special strain towers 135 ft. high. The conductor here consists of a 0.625 in. core of special high-tension steel, with an outer stranding of 20 copper wires, making a total diameter of 0.875 in. The conductors are mounted on a horizontal plane at 20-ft. distances, and each conductor is held by a bank of six parallel strings of insulators through a system of load equalising levers. The ultimate strength of the conductors is 52,000 lbs., and of the insulator groups 60,000 lbs., though it is not anticipated that even under the worst conditions the actual stress will exceed 24,000 lbs. Above each conductor is an earth wire of ½-in. steel, which supports the telephone lines on bracket hangers and also serves as a runway for the inspection cars.

Substations are situated at various places, but the largest is of 60,000-kw. capacity at St. Louis, at the end of the line in a southern direction. The building is of brick and is fire-proof throughout. It is of T plan, 219 ft. long, 63 ft. high, and 150 ft. wide at its widest section. All the high-pressure equipment is installed in the stem of the T, while the apparatus used by the Union Electric Light and Power Company and the United Railways Company of St. Louis is situated in the transept. Since the supply has to be given from separate bus-bars, the sub-station is divided into four separate units, each consisting of three 5,000-kw. 110,000/13,200-volt transformers, which may be operated separately or together. Thus each company can obtain supply over both transmission lines, either of which,

however, is sufficient to take the maximum load of about 66,000 h.p. The incoming lines are supported on a steel framework on the roof, and are thence led to the insulated roof bushings through motor-operated air-break switches. Horn gap lightning arresters are used. In a gallery inside the building are the four groups of oil-switches operated by selective relays in case of trouble on their respective lines. The bus-bars consist of 1-in. copper tube divided into four sections by three oil switches supported from the roof by suspension insulators similar to those used on the transmission line. On the ground floor are seven groups of three single-pole oil switches—four for the transformers and three for the bus-bars. All the high-pressure oil switches are rated at 300 amperes, enclosed in cast-iron cases. They are closed by solenoids energised from a 110-volt storage battery and they open by gravity. Above each of the seven oil switches on the main floor are steel frames supporting switches for isolating the transformer and bus-bar oil switches from the high-pressure bus-bars. The switch rods slide vertically and engage cone slips in the closed position, in which they can be firmly locked by means of bayonet joints. The transformers are rated at 5,000 kw. 95,000/13,800 volts, and are oil immersed and water cooled. They are situated in four separate compartments, each housing three transformers, on one side of the building. Each transformer is set on a truck, so that it may be readily removed from the building for inspection or repair. Each transformer holds about 5,000 gallons of oil and weighs 52 tons, of which the cores account for nearly 30 tons. The connections are delta-delta. Four sets of aluminium cell lightning arresters, one for each 100,000-volt unit, are installed in the gallery.

The low-pressure oil switches are under the gallery on the main floors. The 13,200-volt leads from the transformers are carried on insulating racks beneath the floor to the low-pressure transformer switches. Four bus-bar switches are connected on the low-pressure side of the transformers, and additional oil switches are connected between the bus-bars and the four distributing panels, each of which has five circuits. Part of the energy will be transformed down, or converted to direct current before it leaves the station. Along part of the building occupied by the railway and lighting companies is a switch gallery, giving an unobstructed view of the high- and low-pressure apparatus. Desk-type switchboards are exclusively used. The railway company is installing air-cooled transformers and two 2,000-kw. rotary converters to reduce the pressure to 600 volts direct current, and the lighting company are about to instal a 5,000-kw. 25/60-cycle frequency changer set, in conjunction with which will be a group of 13,200/4,400-volt 60-cycle transformer, aggregating 9,000 kw.

### AN OSRAM IN THE SEA

THE illustration here given shows a 50-volt Osram metal filament lamp, which was recently found in the surf at Langstone Harbour Shore, Portsmouth, by Mr. G. G. H. Ogburn, who was out fishing at the time. The finder noticed that the filament was intact and took it home to test, when he found that the lamp was quite in burning order. He writes, in a letter to the General Electric Co., Ltd. (67 Queen Victoria Street, E.C.): "The lamp had evidently been dropped or washed overboard from some vessel, and had been blown and knocked about till it reached the shore. At the time I rescued it, it was blowing rather hard and consequently the sea was rough."

**University College of South Wales.**—The next session of the engineering department of the University College of South Wales and Monmouthshire, which is a Constituent College of the University of Wales, will begin on October 7th. The courses in electrical, civil, and mechanical engineering qualify for the engineering degree of the University of Wales and the College diploma. For full particulars application should be made to the Registrar, Mr. D. J. A. Brown, University College, Cardiff.

### AN INTERNATIONAL ILLUMINATION COMMISSION

THE International Photometric Commission (sometimes spoken of as the Zurich Commission) was founded in 1900 by representatives of the Gas Industries of America, Austria, Belgium, France, Germany, Great Britain, Holland, Hungary, Italy, and Switzerland. At a session held in Berlin from August 27th to 30th, its scope and powers were amended so that it will now be representative of all institutions and societies associated with the science and practice of illumination. The British delegates in Berlin were Dr. Colman and Mr. Butterfield (Institution of Gas Engineers); Mr. Duddell and Mr. Edgecombe (Institution of Electrical Engineers); Mr. Gaster and Mr. le Maistre (Illuminating Engineering Society), and Mr. C. C. Paterson (National Physical Laboratory).

The Commission is now to be called "The International Illumination Commission." Representation is to be through the medium of National Committees on Illumination in all countries affiliated with the Commission. Each country will have only one vote in all international decisions irrespective of the number of delegates sent, and the contribution from all countries is to be identical in amount. All formal resolutions and documents will be drafted and published in French. Translations may be made into any language by an international committee. English, French, and German are allowed in all discussions. Arrangements were made for appointing committees to consider various technical subjects, so that the real work of the Commission may begin as soon as the new constitution has been approved by the bodies which appointed the delegates.

The officers of the Commission are elected for three years. M. Vautier (Lyons) was elected first President, Herr Weiss (Zürich) becomes Treasurer, and Mr. C. C. Paterson (National Physical Laboratory) was elected Hon. Secretary, so that the Bureau of the new Commission will be located in London.

### CATALOGUES, PAMPHLETS, &c., RECEIVED

**OPAL REFLECTORS.**—A card from Benjamin Electric, Ltd. (117 Victoria Street, S.W.), brings to notice a new design of "Marabella" opal reflectors for use with lamps from 17 to 110 watts capacity. They require no gallery, and are obtainable for concentrating or distributing effects.

**"WIRELESS" DIRECTORY.**—A book entitled "Directory of Amateur Wireless Stations" has been issued by A. W. Gamage, Ltd. (Holborn, E.C.). It contains particulars of amateur experimental wireless stations in Great Britain for both sending and receiving. A copy will be sent to any amateur supplying details of his station.

*Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."*

**PRAT INDUCED DRAFT SYSTEM.**—A leaflet giving particulars of the induced draft system of ventilation for boiler furnaces as developed by Louis Prat (29 rue de l'Arcade, Paris), has been sent us by Mr. S. Utting (4 St. Mary Axe, London, E.C.), who is the British representative of M. Prat. Besides an inducing fan a peculiarly designed chimney of small dimensions is employed. The system is in considerable use on the Continent.

**The Wiremen's Strike at H.M. Office of Works.**—The wiremen employed by the contractors to H.M. Office of Works are still out on strike, and at the time of our going to press the situation is much the same as reported in our last issue. The total of engineering and other electrical workmen on strike is slightly over 300, and, so far as we can ascertain, no serious inconvenience has been caused.

### TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

The annual report of the Meteorological Committee acknowledges the important part played by wireless telegraphy in modern weather forecasting. In this connection 81 messages were received from British warships, and 5,385 from Atlantic liners.

The inspection of the Australian Government's wireless stations at Melbourne, Hobart, and Brisbane has now been made by the Marconi Company under the recent order of the High Court in connection with the pending patent action.

The Telephone and Telegraphic branch of the Department of Railways and Canals in Canada has issued statistics which show that there are now about 400,000 telephones in the Dominion, compared with 200,000 a year ago. The total number of telephones in use works out at one for every 19 persons in the Dominion. The length of telephone wires in use has increased by 200,000 miles during the year, so that the total length is now nearly a million miles. There are 683 companies making statistical returns, compared with 537 the previous year.

The Salonika-Lemnos cable was put into working order again on August 26th last, and on the following day the Cape St. Jacques-Doson cable became once more active. It is not often that telegraph rates are increased in these go-ahead days, but this actually took place in the case of Republic of Colombia, where the rate to places other than Buenaventura was put up 5d.

### ELECTRIC TRACTION NOTES

Frequency changing sets, as referred to in the article on the power supply of single-phase railways in *ELECTRICAL ENGINEERING* of last week, are discussed in some detail in the *General Electric Review* for August. Mr. J. B. Mahoney, of the Connecticut River Transmission Co., Mass., writes that his company is now installing three 3,000-k.v.a. synchronous motor sets in one of the sub-stations for converting the three-phase 60-cycle current of the supply to single-phase 25-cycle current for railway supply. He strongly favours synchronous sets rather than induction motor sets, on account of the better power-factor and the possibility of reversing the operation. Mr. A. E. Pope, of the Power Construction Co. of Mass., describes the use of two exactly similar sets installed in the station of the Boston & Maine Railroad Co. for the supply of power to the Hoosac Tunnel single-phase line. He prefers synchronous motors to induction motors for such frequency changers on account of their corrective effect on the power-factor, and also in the present instance because of the stability of the large 60-cycle system in maintaining the frequency on the tunnel circuits during high momentary overloads. This railway has up to the present been supplied by its own steam station generating single-phase current, but can apparently purchase current transformed from three-phase to single-phase cheaper than it can generate it.

On Monday the Metropolitan Railway Company formally took over the Great Northern and City (Tube) Railway. The extension from Moorgate Street to Lothbury, which was authorised in 1902, will now probably be expedited. The stations are to be renovated, and the service further accelerated.

The linking-up of the District, Bakerloo, Hampstead, and Highgate railways at Charing Cross is expected to be completed by January next.

An hourly all-night service over certain sections of the Manchester tramway system is to be inaugurated to-night.

A special committee is considering the proposals of Balfour, Beatty & Co. for converting the Stirling tramways to electric traction.

## "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

### Specifications Published August 28th, 1913

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

17,867/12. **Detonating Alarms.** W. A. TUFIAEFF and A. DOMANEWSKY. An automatic detonating alarm is arranged so that the strikers have a working movement of about 90°. They are worked by a spring, but are held in check by an electromagnetic lock. A number of cartridges in a drum are struck successively. Eight figures.

18,210/12. **High Pressure A.C. Switchgear.** F. COATES and A. REYROLLE & Co. A condenser is connected in series with the no-voltage release, and a small spark gap is arranged in parallel with the no-voltage coil. Thus step-down transformers are not required. One figure.

18,893/12. **Increasing Frequency of Alternating Current.** M. PLOHL. By a modification of the arrangements described in specification No. 15,744/12 (ELECTRICAL ENGINEERING, June 12th, p. 346), the current with doubled frequency produced in the secondary induction field is introduced in the primary windings to produce a further increase in frequency. These currents are drawn off through tuned circuits. One figure.

19,214/12. **Aluminium Solder.** C. WILLMOTT. A mixture of tin and bismuth is used in proportions between the limits of 12 to one and four to one. The proportions of six to one are generally best. No flux is required.

24,571/12. **Renewable Metal Filament Lamps.** F. HARRISON and F. L. HARRISON. The leading-in wires are continued through the whole length of the stem. The spider has hooked arms at the cap end and specially designed spring gripping arms at the pip end. If hair-pin filaments are used a broken section can be replaced by opening up the pip end of the lamp bulb and inserting a new filament section. Four figures.

25,386/12. **Self-Starting and Lighting System for Automobiles.** J. B. ENTZ. The cell-charging dynamo has sectioned series and shunt windings connected to a multi-contact switch, so that the regulating effect of the series winding may be controlled, and when starting the engine the field windings assist each other without reversal of the connections. One figure.

27,630/12. **Submarine Mines.** F. BÜNDGEUS. The mine is electrically fired by the influx of sea-water when the mine is struck forming an electrolyte for the firing batteries. One figure.

1,395/13. **Resonance Operated Switchgear.** H. W. HAND-  
COCK, A. H. DYKES, and W. DUDDELL. The switches are electro-magnetically operated, and give a positive pull in both "on" and "off" directions by the control circuits being tuned for two different frequencies. A centrally pivoted armature with a magnet at each end may be used. Two figures.

4,522/13. **Self-starters for Internal-combustion Engines.** C. A. VANDERVELL and A. H. MIDGLEY. A belt is driven by an electric motor, and at the same time is brought into contact with the engine flywheel. One figure.

6,292/12. **Telegraph Order Signalling.** H. O. A. JENSEN. The transmitting station contains a primary circuit—battery, key, induction coil—and a secondary circuit connected to the line. A reversing key is used, so that a signal consists of a + and - impulse. Three figures.

10,210/13. **Arc Lamp Electrode.** J. ROUBAL. The electrode has high emissivity, and is not easily oxidised when burnt in an enclosed, but not air-tight, lamp. The carbon, before or after pressing, is impregnated with a mixture of sodium or potassium aluminium phosphate and graphite containing earthy admixtures. Preferably, also, baked calcium saccharate is added to the core.

14,048/13. **Metal Filament Lamps.** A. E. G. To improve the efficiency of metal filament lamps, a substance capable of giving off oxygen at a low pressure when the lamp is burning is introduced in the bulb before exhaustion. Suitable substances are oxides, peroxides, nitrates, nitrites, chlorates, perchlorates, chromates, bichromates, &c., but manganese superoxide and barium chlorate are found specially suitable. The only reaction product is tungsten trioxide, which is practically colourless, and even when deposited on the bulb cuts off but little light. As it is non-volatile, no increase in pressure takes place in the lamp.

### Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free.

Names in italics indicate communicators of inventions from abroad. Summaries of some of the more important of these patents will appear in our next issue.

Cables and Wires, Insulating Materials, &c.: SIEMENS DYNAMO WORKS (*Siemens Schuckert*). [Manufacture of insulated cables or coils] 6,647/13.

Dynamos, Motors and Transformers: BROLT, LTD., BROOKS and HOLT, 18,913/12; A. E. G. [Regulation] 23,372/12.

Electrometallurgy and Electrochemistry: ISLAND [Fixation of nitrogen, 11,363/12; JANSEN [Water sterilizing] 18,207/12.

Heating and Cooking: MARKS (*Landers, Frary and Clarke*) [Heating] 15,958/12; BELLING [Radiator elements] 19,054/12; PIPER and BRIDGWATER [Ovens] 19,064/12; BENNETT [Liquid heating] 28,270/12.

Ignition: LAKE (*J. B. M. Elec. Co.*) [Ignition, starting and lighting systems for automobiles] 18,444/12.

Meters: ELSTER, 4,847/13.

Storage Batteries: RICHARDS [Cases] 223/13; McDougall [Plates] 770/13.

Switchgear, Fuses and Fittings: LAKE (*Le Carbone Co.*) [Connections] 20,357/12; B. T. H. Co. (*A. E. G.*) [Oil switches] 21,867/12; TIRHILL [Regulators] 22,419/12; OTWAY, ORMROD and PURDUE [Shade carrier] 23,520/12; BRITISH WESTINGHOUSE Co. (*American Westinghouse Co.*) [Means for interrupting circuits] 26,809/12; FUSS [Pressure regulators] 28,061/12; TURNER and ROBERTS [Switches] 30,060/12; KRUPP, A. G. [Switches] 3,825/13; DECKER [Motor controllers] 8,878/13.

Telephony and Telegraphy: SHEPARD and McKECHNIE [Alarms for wireless] 11,479/12; SIBLEY [Wireless] 18,422/12; WILLIAMS [Duplex and multiplex wireless] 28,042/12; SCHON [Transmitters for wireless] 5,040/13; MAJORANA [Telephone relay] 10,154/13.

Traction: PERRY [Automatic railway signalling] 4,190/13; PERHSSON [Driving dynamos on vehicles] 16,979/13.

Miscellaneous: B. T. H. Co. (*G.E. Co., U.S.A.*) [Vapour electric devices] 18,371/12; LANGE [Secondary clock alarm] 18,479/12; PARKER [Pendulum and switch for clocks] 21,115/12; SMITS [Restoring equilibrium of inclined bodies] 21,832/12; HARTMANN & BRAUN A.G. [Gyroscope compasses] 6,570/13.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

Distributing Systems, &c.: KETTERING [Control] 7,544/13.

Heating: SIEMENS-SCHUCKERT [Flat irons] 17,665/13.

Instruments and Meters: ROGOWSKI [Measuring magnetic potential between two points] 18,103/13.

Miscellaneous: SCHÜMANN [Alarm for locks] 15,259/13; STANLEY [Insulated receptacles] 17,832/13.

### Expiring and Expired Patents

The following Patent expired this week, after a life of fourteen years:—

17,786 of September 2nd, 1899. **Telegraph Repeater.** S. G. BROWN. A Morse repeater for submarine cables is described. A sliding rotary clutch is combined with a continuously revolving spindle and an arresting device so designed as to retransmit and curb the signals and to interpolate any of the original signalling impulses missed during transmission by a system of positive and negative cams and levers. A tape punching apparatus in which the length of blank tape is limited is also described. There are nine detail drawings.

The following are the more important Patents that have become void through non-payment of renewal fees.

Distributing Systems, &c.: A. E. TANNER and E. A. CLAREMONT [Minimising risk of cable armouring fusing] 11,044/07.

Dynamos and Motors: JOHNSON-LUNDELL ELEC. TRACTION Co. (*R. Lundell, U.S.A.*) [Brush-gear for compounding without sparking] 11,125/03.

Electrochemistry and Electrometallurgy: J. Y. JOHNSON (*Wellman-Scaver Eng. Co., U.S.A.*) [Motor-driven furnace charging gear] 8,665/00; NEW IGNITION SYNDICATE and W. L. SANDY [Electrolyte for primary cell] 10,520/08.

Ignition: A. GAUDIN and E. TELLIER [Gas lamps] 11,301/07.

Incandescent Lamps: B. T. H. Co. (*G.E. Co., U.S.A.*) [Wire sealing-in machine] 10,904/06; H. J. HADDAN (*Bergmann A.-G.*) [Mounting metal filaments] 11,178/07; B. T. H. Co. (*A.E.G.*) [Supporting metal filaments] 10,341/08; H. KUZEL [Metal filaments inflexible when cold] 25,044/08.

Switchgear, Fuses, and Fittings: M. NORDEN [Adjustable combination switch for illuminating signs or signals] 10,856/02; J. H. TRUCKER [Tumbler switches] 11,459/07 and 11,520/07.

Traction: F. C. NEWELL [Combined electro-magnetic rail and wheel brake gear] 9,059/00 and 9,061/00; E. W. TYMMS [Electro-magnetically operated points and signals] 10,962/04.

Miscellaneous: H. W. BUTLER [The capacity of primary cells in which a semi-liquid electrolyte is used is increased by the addition of hemp-cotton, asbestos, &c.] 8,827/00; G. N. HARDEN & SONS and A. V. RUSHWORTH [Watchmen's tell-tales] 10,692/08.

Serious riots have occurred in Dublin, partly owing to the tramway strike. Although there have been secessions of tramway employees in Dublin, and intimidation has been practised to a considerable extent, it appears that an efficient service of trams has been maintained.

The York Electricity and Tramways Committee recommends some extensions to the tramway system. It is also proposed to run trolley omnibuses to Heworth and from Nessgate to Haxby Road.

The receipts from the Newcastle Tramways for the year ending March 31st were £235,321, against £223,565 for the previous year. The traffic expenses increased from £60,663 to £64,493, the general expenses from 17,730 to £18,674, while the cost of general repairs and maintenance decreased from £27,122 to £25,943. The number of passengers carried increased from 49 to 52 millions.

By the addition of three curved junctions, the centre of the city of Liverpool will be connected by an alternative route with the North docks. These alterations were approved by the Tramways Committee last Friday.

A provisional agreement between the Dewsbury Corporation and the National Electric Construction Co. for linking up the Dewsbury Moor and Shaw Cross tramway systems has been approved by the General Purposes Committee, and will be submitted for the confirmation of the Town Council to-day.

The directors of the Aberdeen Suburban Tramways Co. have in view the extension of the system by trolley omnibuses, or else by motor-omnibuses.

## LOCAL NOTES

**Aberdeen: Increase in Power and Heating.**—During the year which ended May 31st last, the h.p. of the motors connected to the mains increased by 1,061, to 7,661, and the number of units supplied to them actually increased by 97 per cent., reaching a total of 2,043,376, exclusive of power to tramways. The supply for heating and cooking increased 36 per cent. to 58,805 units; no less than 743 heating, cooking, and similar devices are let on hire, including 287 irons. A profit of £2,235 was placed to reserve fund.

**Bognor: New Electricity Works.**—The electricity supply, which will be furnished by the Bognor Gas Light & Coke Co., is expected to be ready by the end of the month.

**Clonakilty (Ireland): Local Enterprise.**—The U.D.C. received two tenders for the lighting of the town by 50 50-c.p. lamps. Before these were opened, at the last meeting of the Council, application was made by a solicitor on behalf of a number of townspeople "who had wealth, brains, and great business capacity," and were forming a company, that they might be allowed to tender. This was agreed to.

**Darwen: Combined Power and Lighting Tariff.**—Power of 100 h.p. and upwards will be charged only 1d. per unit for lighting, up to five per cent. of the monthly consumption of power. Above that the ordinary lighting rate of 4½d. will be charged.

**Plymouth: Relief of Rates Again.**—Out of the net profit of £2,542 on the electricity undertaking for the year ended March 31st, £1,000 has been allotted to relief of rates, and the balance to reserve fund. £1,836 spent on mains was paid out of revenue.

**Portishead: Inauguration of Electric Supply.**—Last Thursday a small supply station was started at Portishead, near Bristol. Current is generated by two 100-h.p. Petter semi-Diesel sets. The station will supply both public and private lighting. Distribution is partly underground and partly overhead. The works belong to the Clevedon, Portishead, and District Supply Co., Ltd., whose engineers are Messrs. Christy Bros. & Co., of Chelmsford.

**Stirling: Proposed Purchase of Electricity Undertaking.**—A special committee has now been appointed to consider the question of the proposed transfer of the electricity undertaking to Messrs. Balfour, Beatty & Co., who will also convert the horse tramways to electric traction. It is proposed to acquire the whole electricity undertaking for a cash payment.

**Warrington: St. Helens-Sankley Canal Bridge.**—The Warrington Corporation have been asked to supply power for working this bridge, and are seeking consent of the intervening smaller Local Authorities to lay the necessary mains through their areas.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

### Generating Stations, Sub-Stations, Mains, &c.

**Accrington.**—The Corporation is about to apply for sanction to borrow £3,050, of which £2,500 is for consumers' high-tension sub-station equipments, switchgear, transformers, and service cable. Sanction has been received to borrow £1,060 for main and £940 for switchgear and transforming plant.

**Australia (Sydney, N.S.W.).**—100 3-pole contact and suspension gears for "Metroflame" arc lamps for City Council.

**Belfast.**—The Council has decided to enter into a preliminary agreement with the Belfast Harbour Commissioners to lease a large amount of additional ground for extensions of the electricity works.

**Bingley (Yorks.).**—An L.G.B. inquiry has been held in connection with a proposed sub-station for electricity supply and tramways. Power in bulk will be taken from the Keighley Corporation.

**Cuba.**—A number of concessions to instal electric generating plant have been granted to various gentlemen in Cuba. The *Gacetas*, containing further information, may be seen at the Commercial Intelligence Branch of the Board of Trade.

**Galashiels.**—The Council has considered it inadvisable to lay down a municipal electricity works, but the Galashiels & District Electricity Supply Co. has been now formed, and will apply for a Provisional Order. It is anticipated that a considerable amount of power will be required by the mills in the district.

**Haslingden.**—The Electricity Committee is about to obtain estimates for laying a cable to Helmshore.

**Hornsey.**—An L.G.B. inquiry is to be held to-day regarding the proposed purchase of land for a sub-station at Fortis Green.

**Knaresborough.**—On the recommendation of the Gas Committee, the U.D.C. have agreed to the erection of a small turbine electricity supply station on the River Nidd.

**Newport (Mon.).**—The L.G.B. inquiry with reference to the proposed extensions of the electricity works was held last week. A 25-year loan was asked for, but the Inspector (Mr. T. C. Ekin) said that the generating plant, foundations, and switchboard would only carry 17 years, and the motor-generator 15 years.

**Plymouth.**—Various cable extensions.

**Russia.**—The St. Petersburg Electric Lighting Co. has formed a subsidiary company to develop the supply in Petersburg-Semstvo.

**Sheffield.**—The L.G.B. has sanctioned a loan of £79,700 for extensions at the Neepsend electricity works.

**Sileby.**—In view of the high price of gas, inquiry is to be made as to the cost of electric supply for public and private lighting and power.

**Tyldesley.**—Certain streets are to be lighted by metallic filament lamps.

### Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

**Barmouth.**—Sanatorium. Executive Committee of the Welsh National Memorial to King Edward VII.

**Belfast.**—Extensions to Royal Victoria Hospital. Architects, Young and Mackenzie.

**Burnley.**—New schools for Education Committee.

**Bury.**—New police station, &c.

**Chelmsford.**—106 artisans' dwellings. Town Council.

**Darlington.**—Extensions at Workhouse. Board of Guardians.

**Droylsden (near Manchester).**—An electric lighting installation is proposed for Droylsden Church. The Rector.

## THE RECORD ELECTRICAL Co., Ltd.

**Dublin.**—Premier Picture Palace (Dublin), Ltd. Secretary, John Carley, 42 Dame Street.

**Eastbourne.**—Hospital at Gildredge Underhill. W. C. Field, Borough Surveyor.

**Garstang.**—New hospital. Rural District Council.

**Glasgow.**—Large hospital (£60,000) at Robroyston. Corporation Health Department.

Extension of Municipal Buildings.

**Grantham.**—New Council school. Borough Surveyor.

**Leigh (Lancs.).**—118 cottages to be erected by Corporation.

**London: Islington.**—The Board of Guardians have appointed a Committee to inspect workhouses in other districts to obtain information on electric lighting.

**Harrods' Stores.**—New buildings costing £150,000.

**Middleton.**—Proposed hospital, to cost £20,000.

**Mossley.**—Proposed Livingstone School. Architects, Winder & Taylor, Oldham.

**Nelson.**—Proposed Corporation abattoirs, to cost £20,000.

**Penzance.**—Council school at Lesendjack.

**Rotherham.**—Miners' Institute and Hall, Parkgate. Architect, J. Platts, High Street, Rotherham.

**Stockport.**—Extension, Co-operative Drapery Department, Chestergate. Architects, Messrs. Wrathmell & Blackshaw, Stockport.

**Sunderland.**—New Bede Collegiate Boys' School. Council.

### Miscellaneous

**Argentine.**—Mr. P. Farquhar, of the Argentine Railways Combine, is reported to have stated that his syndicate intends to electrify the North-West Argentine Railway, which belongs to the Cordoba Central Company.—The Central Uruguay Railway has applied for permission to electrify its line between Cordon and Manga.

**Australia.**—Ammeters, voltmeters, &c.; telephone parts; switchboard parts. Deputy Postmaster-General, Sydney, October 15th. Particulars from High Commissioner in London for the Commonwealth, 72 Victoria Street, S.W.

Preparations are being made by the Chillagoe Co., Ltd., to equip the Mount Mulligan (Q.) coal mines with electrical hauling and other plant.

**Dundalk.**—A number of extra 75-c.p. lamps for public lighting are required. Mr. P. A. Spalding estimates the entire annual cost per lamp to cover current and maintenance at £4 10s.

**Hong Kong.**—The American Consul-General reports increasing demands for all classes of small electrical apparatus and supplies, particularly fans and heaters. 100-volts A.C. 72 cycles. Also strong demand for self-contained electrical installations from 60 to 30,000 lights.

**Italy.**—Electrification of the Genoa-Ovada-Asti railway.

**Russia.**—According to the *Torgovo Promyshlennaya Gazeta* (St. Petersburg), P. A. Popov and A. N. Rukin are seeking sanction to form a company for a 35-mile electric railway from Moscow to Voznyesensk.

**Salisbury (Rhodesia).**—The Municipal Council has established a showroom for domestic electrical appliances, and invites manufacturers to send samples for exhibition. Further particulars from the London agents, Davis & Soper, 54 St. Mary Axe, London, E.C.

### TENDERS RECEIVED AND ACCEPTED

**Accrington.**—The following tenders have been accepted:—W. T. Glover & Co., Ltd., for 0.1 and 0.05 sq. in. extra high-tension three-core paper lead-covered armoured cable; British Thomson-Houston Co., Ltd., for switch panels; Bruce, Peebles & Co., for a 250-kw. motor converter; British Westinghouse Electrical Manufacturing Co., Ltd., for two 100-k.v.a. 6,000:400-volt static transformers and one oil switch.

**Australia.**—The tender of Willams & Robinson for condensing plant, turbo-alternators, transformers, and motors for the Perth (W.A.) Power Station has been accepted. Four sets of rotary converters have been ordered from the British Westinghouse Co., and Babcock & Wilcox have obtained the order for boilers and equipment.

The tender of Siemens Bros. Dynamo Works for arc lamp carbons has been accepted by the Sydney (N.S.W.) Council.

**Rotherham.**—Siemens Bros. Dynamo Works have obtained through Messrs. Smith Bros., Rotherham, a yearly contract for the supply of "Tantalum" traction lamps for the Rotherham Corporation Tramways.

**South Africa.**—The tender of the B.T.H. Co. for a turbo-alternator, condenser, kinetic pumps and accessories, and of Bruce, Peebles & Co. for a motor-converter, is recommended for acceptance for the Cape Town Electricity Works.

### APPOINTMENTS AND PERSONAL NOTES

The salary of Mr. A. J. Beckett, Borough Electrical Engineer, Bridlington, has been increased from £350 to £400.

Lecturer in Electrical Engineering required for Queensland (Australia) University. (See advt.)

Linemen and Assistant Linemen required with experience of trolley line work. (See advt.)

### MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. G. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £74 to £74 10s. (last week £73 to £73 10s.).

**Nathan and Allen.**—Messrs. F. B. Nathan and F. S. Allen have opened an office and showroom at Queen Anne's Chambers, Westminster, S.W. They represent the Kartret Engineering Co., who manufacture switchgear, and the Wardle Engineering Co., Ltd., makers of lanterns and fittings for streets, ships, and works.

**Change of Address.**—Brotherton Tubes & Conduits, Ltd., have moved into larger premises at 4 Carr Street, Blackfriars, Manchester, under the management of Mr. T. A. Nunwich, who also represents the Wandsworth Electrical Manufacturing Co., Ltd., and Messrs. Pritchetts & Gold, Ltd., in Lancashire, Yorkshire, and Cheshire.

**Removal.**—Messrs. L. E. Wilson & Co. (20 Cross Street, Manchester) are moving on September 8th to 10 Corporation Street, Manchester. Their telephone number will be City 344, and telegraphic address "Telephony" Manchester, as at present.

**Companies Struck off Register.**—The names of the following have been struck off the register of joint stock companies:—Dynelectron Syndicate, Ltd., Electrical and Mechanical Exhibition, Ltd., Electric Coin Freed Meter Dimming Syndicate, Ltd., Electric Tramways Trust, Ltd., Hirst Magneto Co., Ltd., Schreiber Electric Battery Co., Ltd., Vulcan Dynamo and Motor Co., Ltd.

**Liquidations.**—A general meeting of the Gilbert Arc Lamp Co. will be held on October 7th, at 3 Fenchurch Street, E.C., at 3 p.m., to hear the Liquidator's report.—A general meeting of the Doncaster Electrical Co., Ltd., will be held on October 8th, at 37 Manor Road, Bradford, at 11 a.m., to receive the Liquidator's report.

**The Producer Gas Plant at Accrington.**—We regret that the output of the new producer gas-driven alternators at the Accrington Electricity Works was given as 12,000 to 15,000 units per week, instead of 120,000 to 150,000 in the detailed description of the plant in our last issue.

**University College, London.**—A course of post graduate lectures on "Conductors for the Electrical Transmission of Energy," will be delivered by Professor J. A. Fleming at University College (Gower Street, W.C.), on Wednesdays at 5 p.m., commencing on October 29th. These lectures may be attended by members and non-members of the University, and the subject is divided into two parts: (1) deals with telegraphy and telephony, and (2) deals with light and power.

**The Advantages of Ozonisers.**—Physiological and psychological tests undertaken by the Society of Heating and Ventilating Engineers in America have shown that a roomful of school children can work at full efficiency and comfort, says the *Electrical World* (New York), breathing the same air three hours or more at a time, if that air is properly circulated and deodorised by being passed through an ozoniser. These experiments are thought to place on a scientific basis the fact long suspected that the usual empirical allowance for ventilation has no relation whatever to the actual physiological needs of the human system.

Small Advertisements and Official Announcements, Wednesday first post.

Displayed Advertisements, Tuesday first post.

Corrections in Standing Advertisements, Monday first post.

All letters to be addressed to "Electrical Engineering," at the EDITORIAL AND PUBLISHING OFFICES: 208-206, TEMPLE CHAMBERS, LONDON, E.C.

Telegrams: "Circling, Fleet, London."

Telephone No.: 5509 Holborn.

Cheques to be made payable to THE KILOWATT PUBLISHING CO., LTD., and to be crossed LONDON COUNTY AND WESTMINSTER BANK (Temple Bar Branch).

## SUMMARY

SOME notes on the arrangements for the next session and other matters relating to the Universities and Technical Colleges are given. (Page 512.)

THE strike of electrical wiremen engaged by contractors to H.M. Office of Works has collapsed, and the men have resumed work. (Page 512.)

THE Annual Report of the International Electro-technical Commission for the year 1912 has been published. The Commission has just held its second plenary meeting in Berlin. (Page 512.)

A 30,000 volt underground cable distributing system has been installed by the Berliner Elektrizitäts-Werke for the supply of Greater Berlin. It comprises 144 miles of cable, connecting up fifteen sub-stations, transforming down to 6,000 volts for the secondary underground networks. Particulars of the sub-stations and of the cable are given. (Page 513.)

SOME new shades and reflectors and a new design of radiator are described and illustrated on page 514

WE publish a description of the alterations which are to be made in the switchgear of the L.C.C. tramways power house at Greenwich. Interesting features are the use of three single-core cables for the generators to the switchboard, so as to do away with trifurcating boxes, and the application of reactance coils to diminish the effects of surges. (Page 515.)

THE change of connections necessary to effect the reversal of rotation of an induction motor without changing over the mains is dealt with. (Page 516.)

WE give some details of a new system of electric traction which will be put into operation in the United States shortly. Current will be supplied to the locomotives at 11,000 volts 25 cycles, and will be converted to 2-phase 750 volts for the motors.—The Bristol Corporation are recommended to apply for powers to work the electric tramways with a view to taking over the local company's undertaking.—The Municipal Tramways Association Conference will be held at Sheffield from Sept. 23rd to Sept. 26th. (Page 517.)

THE Western Electric Co. has received a tender for a number of full automatic telephone exchanges in New Zealand.—An exchange on the Western Electric Co.'s system will also be opened shortly in Darlington.—The Pacific Cable Board's accounts for the year to March 31st show a balance of £14,157 to be carried forward.—The Australian Government has spent £40,000 of the £50,000 voted for wireless telegraph purposes. (Page 517.)

A NUMBER of patent specifications relating to different phases of wireless telegraphy were published by the Patent Office last week. A new design of mercury vapour lamp has been protected by the B.T.-H. Co.—A specification by C. R. Belling describes a strong heating element, and another by H. J. Piper and R. A. Bridgwater describes a thermal storage oven.—An improved construction of Tirrill regulator is also covered by a patent. (Page 518.)

IT is proposed that the Leeds Corporation shall purchase the Roundhay Electric Lighting Co.—Messrs. Balfour, Beatty & Co. have been asked for details of their offer to purchase the Stirling electricity works.—It is once more suggested that the Redditch electricity undertaking should be sold.—A sum of £300 is to be transferred to relief of rates from electricity profits at King's Lynn.—A Board of Trade inquiry is to be held concerning cable breakdowns at Hebburn.—The Middleton Corporation has agreed to the Lancashire Electric Power Co. supplying a large consumer in their district. (Page 519.)

GENERATING plant and mains extensions are contemplated at Carlisle (£4,300); Eastbourne (£3,000); Plymouth (£5,500); Bacup (£1,800); Cardiff (£30,500); Salford (£2,000); and Leek.—A complete power station equipment is required at Ilkley, and electric lighting schemes are under consideration in a number of places.—A wet-air filter is to be installed at Worcester, and electrically-driven centrifugal pumps at Wolverhampton.—Electric cranes are required in Greece, and telephone material in Australia. (Page 519.)

AN interim dividend at the rate of 6 per cent. per annum has been declared by the British Electric Transformer Co.—Considerable progress continues to be shown by the Clyde Valley Electric Power Co. (Page 520.)

## UNIVERSITY AND TECHNICAL COLLEGE ANNOUNCEMENTS

THE prospectus of part-time (evening and apprentices' day) courses in electrical and mechanical engineering at the Manchester Municipal School of Technology shows that a very complete course of instruction in general electrical work may be undertaken in the evenings by students engaged in practical engineering during the day. The evening "Associate Course" is arranged to cover a year's training, and each year's course is more advanced than the preceding one. Certificates are granted on the satisfactory completion of one of the many prescribed courses. These certificates are endorsed by the Board of Education. The examinations of the City and Guilds of London Institute may also be taken. Special courses on telephony and telegraphy, wireless, and wiring and fitting are also provided, and the theoretical instruction is well amplified by work in the extensive laboratories of the College. Professor Miles Walker is head of the electrical engineering department, and the Principal is Mr. J. C. Maxwell Garnett. The part-time courses will begin on September 22nd.

The evening classes at the Borough Polytechnic Institute (Borough Road, London, S.E.) will reopen on September 22nd, when wiremen's work and electrical design and workshop practice may be studied. In addition there is a four-years' course beginning with general principles (for beginners) and leading to a study of alternating-current work, including instruments and machines, &c. The head of the department is Dr. John Henderson. Further particulars may be obtained on application to Mr. C. T. Millis, who is the Principal of the Institute.

## THE INTERNATIONAL ELECTROTECHNICAL COMMISSION

THE second plenary meeting of the International Electrotechnical Commission was held in Berlin last week, and some 70 delegates were present. Dr. E. Warburg presided in the absence of Dr. Budde, and Dr. Lewald welcomed the Commission on behalf of the German Government. The list of 80 definitions proposed by the Nomenclature Committee was adopted, and German and Spanish equivalents are to be added. The recommendations mentioned below as to a standard of copper were adopted, and on the recommendation of the Italian engineers, certain definitions dealing with the terminology of water-power plants were agreed to, together with a list of symbols. There was a prolonged discussion on the question of rating of electrical machinery, and some outstanding points have been referred back to the National Committees. M. Maurice Leblanc was elected President for the next two years, and the Hon. Sec., Col. Crompton, and the General Secretary, Mr. le Maistre, were re-elected.

The fourth annual report, which covers the year ended Dec. 31st, 1912, has just been issued. The actual report, in English and French, is prefaced by a frontispiece consisting of a reproduction of a portrait of Faraday painted by Beatrice Bright, in possession of Dr. E. Budde, the present President of the Commission. The report sketches the history of the Commission from its inception in 1904, and refers to the meeting held last week in Berlin and the forthcoming meeting in 1915 in San Francisco. Committees are now established in twenty-one countries, and several other countries are taking interest in the work. Mention is also made of the special committees on nomenclature, symbols, rating and prime movers, and brief summaries are given of the nature of the work which is being taken by each. The question of an international standard for copper is being considered, and recommendations have been drafted by the Directors of the National Laboratories at Berlin, London, Paris and Washington. An important proposal that was brought forward for ratification at Berlin was that the kilowatt should be adopted as the industrial unit of mechanical as well as electrical power. The symbols committee has already definitely adopted the letters I, E, and R for current, E.M.F. and resistance, and has standardised the counter clockwise direction for advance of phase in circle diagrams. A good deal of information as to the constitution and activities of the various national committees is included in the report.

**Half-watt Lamps.**—We are asked by the General Electric Co., Ltd., of 67 Queen Victoria Street, E.C., to state that the Osram Works are at the present time manufacturing half-watt lamps under full patent rights, and will be in a position to place these lamps on the market in the very near future—"at least as early as any of the other firms entitled to manufacture this type of lamp."

## THE WIREMEN'S STRIKE

THE strike of wiremen employed by the contractors to H.M. Office of Works, came to a conclusion on Monday, and the men on strike returned to work on the same conditions of pay, &c., as before they went out on strike. This course was decided upon by a ballot among the strikers on Saturday, which gave a considerable majority in favour of the resumption of work. It is stated that the men were handicapped by want of funds, and that regular strike pay was not distributed. The causes of the strike were fully given in an article which appeared in our issue of August 28th. There had previously been some dissatisfaction among the engineering labourers, who had applied for an increase of pay from 7d. to 7½d., which was recently accorded to the builders' labourers. The Office of Works offered to refer the matter to the Board of Trade for arbitration, but in the meantime the painters' strike occurred, and the engineering labourers struck "in sympathy," and the wiremen came out with them. We understand that the arbitration with regard to the engineering labourers' wages will be proceeded with in the ordinary course.

Last Thursday a number of daily newspapers published a communication which had been sent them by the Strike Committee, to the effect that the wiring of the official residences of the Prime Minister and the Chancellor of the Exchequer in Downing Street had been left in a dangerous condition owing to the strike. We regret to say that *The Times*, *Daily Telegraph*, and other papers of good repute, published this statement without first taking the precaution to ascertain whether it was correct. *The Morning Post*, however, made inquiries at the Office of Works, where they were informed that the statement in question was untrue.

The work that is being done at the two houses in question is to modernise the electrical installations, which are about twenty years old, but their insulation resistance was good and there was absolutely nothing in them which constituted a serious fire risk. Had there been any risk of this sort, it is fairly obvious that the officials at the Office of Works would have simply drawn the fuses.

Apparently among the majority of daily newspapers any news which has to do with "electrical" subjects is only suitable for publication if it is of a sensational character, and accuracy takes a second place, or no place at all. The daily Press already knew by that time that they had been misled previously by the strikers' deliberately incorrect announcements, and yet they accepted this piece of "news" on the same authority without any endeavour to obtain confirmation of it. We referred to some of the previous misstatements in our issue of August 28th: another will possibly amuse our readers. It was announced that, in some of the rooms of the L.G.B. Offices, work was done by candle-light, owing to the electric supply being cut off. On inquiry we find that in one room only (in which one or two female typists are employed) candles were requisitioned, and examination showed that the cause of the "electric light failure" was merely that the circuit switch was off.

**The Co-ordination of Electric Supply.**—Under the auspices of the Industrial Committee of the Institution of Electrical Engineers, Dr. Klingenberg, of Berlin, will deliver an address on Thursday, December 4th, on the "Co-ordination of Electric Supply in Big Cities with special reference to Chicago, New York, Berlin and London." Although the address will be followed by a discussion it is not regarded as an ordinary paper, and will not be printed in advance.

**Obituary.**—We have to record with regret the death from heart failure on Aug. 29th, at a sanatorium at Homburg, at the age of sixty-eight, of Prof. H. Aron, whose name is so well known in connection with electricity meters. Prof. Aron established the Elektrizitätszählerfabrik of Charlottenburg. He had been for many years a worker in electro-technical matters, but is best known for the differential pendulum type of meter which bears his name. He also developed a system of electric clocks, and a design of taximeter for cabs. He was a native of Posen, but was educated chiefly in Berlin, where for ten years he held the post of lecturer in electrical measurements. He was also at one time a teacher of physics in the Artillery and Military Engineers' School.

**An Electrical Fatality.**—A curious case is reported from America, in which a motor-car running at a very high speed collided with a telephone pole alongside some overhead power lines. The pole is reported to have been carried some 30 feet, and the car became mixed up with the power lines which had been brought down, with the result that one of the occupants received a fatal shock and others were taken unconscious to the hospital.

## THE 30,000-VOLT CABLE DISTRIBUTION SYSTEM OF GREATER BERLIN

IN order to reach the outlying districts of Berlin in an economical manner, the Berliner Elektrizitäts-Werke have a 30,000-volt underground cable distribution network comprising 144 miles of three-core cable ( $8 \times 0.0775$  sq. in.), in the form of two ring mains, one north and the other south of the Company's large power station at Oberspree, Oberschöneweide. The following description of the system and the cable itself have been compiled from articles which have appeared in the *Elektrotechnische Zeitschrift* and *Elektrische Kraftbetriebe & Bahnen*. The south ring has three branch mains, two of which are connected at their extremities, forming a third ring. There are fifteen large (30,000/6,000-volt) transformer stations connected into these circuits, and a number of small (6,000/220-volt) stations on

FIG. 1.—SECTION OF 30,000-VOLT ( $3 \times 0.0775$  sq. in.) CABLE. HALF SIZE

the secondary networks. The total number of substations is 240, of which 195 are in the form of kiosks containing each two 60-kw. transformers stepping down from 6,000 volt to 220 volt. Both the 6,000-volt and 220-volt networks are underground cable.

The generating pressure at Oberspree is 6,000 volts, and this is stepped up to 30,000 volts for the above system in a transformer house, which has been erected adjacent to the station. This building is constructed for a total transformer capacity of 32,000 k.v.a., but at present only three of the six transformers are installed. They are three-phase transformers, oil-insulated, and as clean water was not available, all the transformers, both those in the step-up substation and those in the fifteen step-down substations, are provided with forced-draught ventilation. The transformer oil-tank of corrugated iron is surrounded by a sheet-iron cylinder, and air

FIG. 2.—30,000-VOLT CABLE DIVIDING BOX.

is blown through the intervening space. At the main substation there are three sets of ventilators each delivering 1,000 cubic meters of air per minute into an air duct, with a

branch to each transformer. Dampers are provided so that the air flow can be regulated or stopped entirely in case of fire. The air is drawn through a rough filter consisting of ninety-five boxes of wood-wool arranged (in parallel) in a steel frame. The 6,000-volt sides of the transformers at the step-up substation are connected direct to the main station bus-bars, and only the 30,000-volt switchgear is in the transformer house. The transformers are in separate fire-proof cells with roller-shutter doors opening on to an outside platform, from which the transformers can be run off on to a truck for transporting to the repair shop. In each transformer, the temperature of the oil is registered by a thermometer in the power station.

The 30,000-volt bus-bars on the first floor of the building are divided into three divisions, from each of which two cables go out, one to the north ring and one to the south. In the oil switches, which are on the ground floor, the contacts for the three phases are in separate oil chambers. The circuit is made and broken through resistances connected to auxiliary contacts, the resistances being arranged outside the oil chambers. The switches are closed by hand through chain gearing, but are opened by direct-current releasing gear.

A system of differential protection has been adopted for both transformers and cables, but no details are given. It is mentioned, however, that the capacity current of the pilot cable in event of a short circuit on the system was so great that it operated the relays, although the cable protected by this pilot cable was intact. This effect was prevented by the installation of reactance coils. An apparatus is installed in connection with these differential relays to indicate at the power station when any cable section has been cut out; there is a different indication for each section, and the fault is easily located.

The 30,000 volt cable itself is illustrated in Fig. 1. Its three conductors are each  $19/1.84$  mm., giving 50 sq. mm. section. The radial thickness of the impregnated paper insulation between cores and between core and lead is 1.6 mm., and the thickness of the lead 3.6 mm., giving a diameter over the lead of 74.7 mm. The total diameter over the jute-covered strip armouring is about 90 mm., or 3.55 inches. Each length, after immersion in water for 24 hours, was put under a test pressure of 75,000 volts three-phase for half an hour, and this was tested for the same period at 75,000 volts (single-phase) between the three cores and the lead covering. A momentary test was also made at 90,000 volts, i.e., three times the working voltage. Insulation tests were made on each length before and after these high-voltage tests to see that they had not affected the dielectric. Tests on 10-metre lengths of cable under oil showed that the application of 250,000 volts for a short period did not puncture the insulation. The constants of the cable per kilometre and per phase at  $15^{\circ}$  C. were:—Resistance, 0.35 ohm. (0.564 ohm per mile); three-phase capacity, 0.13 microfarads; self-induction, 0.36 millihenry; insulation resistance, 700 to 1,000 megohms.

After the whole cable system was laid, a 60 km. ( $37\frac{1}{2}$  miles) section was run for half an hour at 50,000 volts, this pressure being obtained by over-exciting a generator at the Oberspree station, thus running the whole plant, comprising generator, switchgear, transformers, and cable network, at 66 per cent. excess pressure. It is interesting to note that the transformers were so highly saturated at this pressure that the magnetising current compensated for the capacity current of the cable system, and the generator actually worked with a lagging current. To determine the power-factor of the cable and the dielectric losses, a Duddell-Mather (torsion-dynamometer) wattmeter was employed. At 30,000 volts, 25 cycles, the charging current of the 60 km. length of cable was 44 amperes, the apparent power 2,280 K.V.A., and the watt-power 45 kw., corresponding to a power-factor of only 0.02, or 2 per cent., but after deducting the estimated value of the C<sup>2</sup>R loss due to the charging current, the dielectric hysteresis loss is estimated at only 5 kw.

The short-circuit test showed that the resistance to alternating current at 25 cycles was 1.8 per cent. greater than for direct-current; at 50 cycles some 6.5 per cent. greater. A temperature test, running 24 hours at 90 amperes, 24,000 volts A.-C. (i.e., a current density of 1,160 amperes per sq. in.), showed a temperature rise as measured by resistance of only  $7^{\circ}$  C.

The whole 30,000 volt system has been in operation for nearly two years without mishap. A landslide produced two bad kinks in the cable at one point, but the cable held out for weeks, until that section was relaid.

The capacity current of the whole 30,000-volt network is 162 amperes, corresponding to an apparent load of 8,350 k.v.a. This enormous capacity current has a highly beneficial influence on the power factor of the system during working hours. The step-down substations are similar in design to the substation described, except that 65-volt storage batteries of 37-ampere-hour capacity are installed for operating the switch-releasing gear. These are charged by small motor-generator

sets. The substation lights can be switched over to the battery in cases of emergency. There are in all thirty-six dividing boxes on the 30,000-volt system. As shown in Fig. 2, these are of ample size, with long smooth porcelain insulators which will not collect dust, and give a long creepage surface. Bare copper rods run from these to the isolating links which are on similar insulators.

The cable is laid direct in the ground, about 3 ft. deep, and the telephone and pilot wires are laid in the same trench. It is protected by a ferro-concrete casing. 1,500 straight-through connecting boxes of the pattern illustrated in Fig. 3 are used on the network.

FIG. 3.—30,000-VOLT CABLE CONNECTING BOX.

This comprises a sweated-up lead sleeve enclosed in a split cast-iron box. The cores at the joint are not separated by distance pieces, as has been usual, but are enclosed in cylinders of impregnated paper. Both the inner lead sleeve and the outer iron box are filled with insulating compound. Special joints made in this way were tested for hours at three and four times the working pressure before the method was applied to the joints on the system.

Great care was exercised, in the installation of both these and of the dividing boxes, to exclude all air before filling up, and a vacuum apparatus was employed for the purpose.

### NEW VELURIA GLASSWARE

SOME new designs of shades made of the pleasing "Veluria" white translucent glass have recently been placed on the market by the British Thomson-Houston Co., Ltd. (Mazda House, 77 Upper Thames Street, E.C.). Two of these are illustrated below.

The two patterns illustrated have raised decorations of a distinctly novel appearance, and they are made for Mazda lamps of from 10 to 40 watts. Another pattern has the same contour and reflective characteristics as the standard "intensive" type of Veluria shade, but has the addition of an etched floral design. This reflector is made in four sizes to take Mazda lamps ranging from 10 to 100 watts.

### CATALOGUES, PAMPHLETS, &c., RECEIVED

**THE I.C.S. STUDENT.**—The September number of this little publication, which, as many of our readers already know, is published monthly by the International Correspondence Schools, Ltd. (Kingsway, London, W.C.), for circulation among their old and new students, contains considerable information which should prove of use to those concerned. Among the articles of electrical interest we notice one entitled "Notes from a Wireless Operator's Diary."

**RAILOPHONES.**—The von Kramer inductive wireless system of telephoning and telegraphing to moving trains from a fixed point is fully dealt with in a publication which has been issued by International Railophones, Ltd. (Prudential Buildings, Corporation Street, Birmingham). The system was illustrated and described in *ELECTRICAL ENGINEERING* for July 11th, 1912, p. 395. A section of line has been experimentally equipped in Germany, and the company invite the British railway companies to try

some of the various modifications of the system over a short length of track.

**"G.E.C. MONTHLY LIST."**—As the General Electric Co., Ltd. (67 Queen Victoria Street, E.C.), have found it difficult to keep their customers posted with all the latest information regarding the introduction of new patterns, alterations in designs, &c., they have decided to issue monthly a gummed and perforated list so that the recipient may insert the various parts against the particular pages of the G.E.C. sectional catalogue to which they refer. The list this month deals with a new pattern of "Geeko" double-line auto-reset inter-communication telephones for wall or table, some new trembler bells, and also wall nails for wiring work.

*Readers desiring copies of catalogues or pamphlets should apply to the firms in question, referring to the notice in "Electrical Engineering."*

**ELECTRIC LIGHT FITTINGS.**—Some very artistic designs of electric light fittings are contained in a catalogue of Dutch hand-made art metal ware from the "Cuprera" Art Metal Works at The Hague. The sole agents for Great Britain and the Colonies for these products are D. N. Dobson & Co. (93 Aldersgate Street, E.C.).

**SHADES AND REFLECTORS.**—A new leaflet is being circulated by Siemens Brothers Dynamo Works, Ltd. (Tyssen Street, Dalston), dealing with a new style of opal reflector under the name of "Marbella." These reflectors have a pleasing appearance, and are very efficient; they eliminate glare, and give a pure, soft, white light. Owing to their design and the fact that there are no frosted or ground surfaces or angular corners, they are exceedingly easy to clean, and do not collect dust. They are made in concentrating and distributing types. Galleries are unnecessary, as these reflectors have a  $1\frac{1}{2}$  in. hole fitting. The leaflet also calls attention to the "Holophane Benjamin" steel reflectors, which are specially adapted to industrial purposes.

### A NEW DESIGN OF HEATER

WE have received from the Edison & Swan United Electric Light Co. (Ponders End, Middlesex) particulars of a new design of quartz heater, made under the Bastian patents, which they are introducing for the coming season. This heater, which is contained in a well-made brass case of elegant design, is suitable for use in drawing-rooms, boudoirs, first-class state-rooms aboard ship, or any superior apartment. It is usually fitted with two switches and twelve Bastian glowers of 1,500 watts capacity, but the same pattern

NEW DESIGN OF BASTIAN HEATER.

can be supplied fitted with eight glowers only of 1,000 watts capacity. Each heater is supplied with 2 yds. of flexible. The overall height is 19 in., the depth is 5 in., and the breadth 12 in. The weight is only 10 lb. The twelve glower pattern takes from  $\frac{3}{4}$  to  $1\frac{1}{2}$  kw., and the eight glower pattern takes from  $\frac{1}{2}$  to 1 kw. Our illustration gives a good idea of the neat appearance.

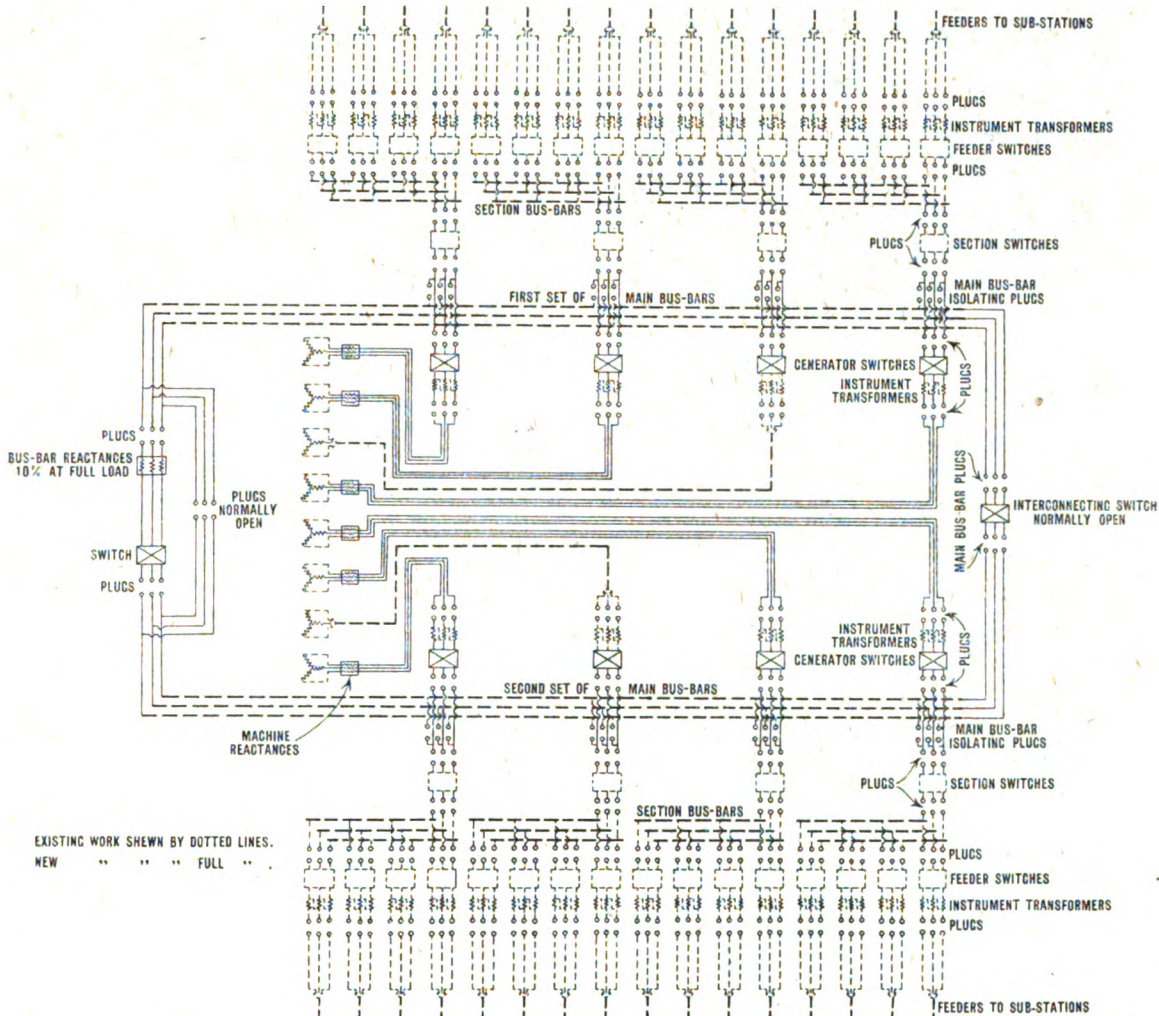

## SWITCHGEAR ALTERATIONS AT THE GREENWICH GENERATING STATION OF THE L.C.C. TRAMWAYS

AS announced in our issue of August 21st, the London County Council have invited tenders for a somewhat extensive alteration to the main switchgear at their generating station, Greenwich, and an outline of the modification proposed may be of interest. The switchgear was constructed in 1905 and at the time was considered one of the finest examples of high-tension gear, and it may be somewhat surprising to find that modifications are required so soon. Through the courtesy of Mr. Fell we have obtained a copy of

thickness of 0.4 inch. Although each phase is thus surrounded by a metallic sheath, the induced currents in the lead at a frequency of 25 cycles per sec. are found to be negligible, and the segregation of the conductors into three separate cables adds to the safety of the system by removing the necessity of providing trifurcating boxes and by eliminating joints on all three phases in close proximity to each other. An inspection of the diagram will show that, in the cases of Generators 3 and 4, the original cables are being retained, but when these engine generators are discarded and turbo-generators are substituted, machine cables of the same character will then be provided.

The capacity of the generator oil switches is being

the specification outlining the work for which tenders are now invited, and place before our readers the salient features of the scheme.

The switchgear was originally laid out in 1903 for eight generators of 4,000 kw. capacity each, and four of these generators were originally installed. At a later period, when extensions became necessary, turbo-generators of 5,000 kw. capacity were fixed in place of the reciprocating units originally contemplated. In common with most users of turbo-generators of large size, the Council's engineers have experienced trouble on short circuit, and the effect of 30,000 kw. plant capacity behind the short has been in several cases somewhat disastrous, so much so that a modification of the switchgear has been considered desirable.

A general lay-out of the switchgear of the station is shown on the diagram above, and the alterations are also indicated. In the first place, the existing three-core lead-covered cable and cable boxes connecting the machines to the switchgear, and the various parts of the switchgear to one another, are being replaced by single-core cables insulated with paper to a radial

increased to render them capable of breaking heavy currents on short circuit. This is being done for each generator, and at the same time two massive oil switches are being provided for interconnecting the two halves of the bus-bars. It will then be possible to run the two halves of the station as separate systems, and duplicate synchronising gear will be required for coupling the halves together. One of these interconnecting switches will normally be kept open, but the other will be used for dividing the system in cases of accident, and to render the disrupting effect under short circuit less harmful, reactance coils will be provided in series with the switches.

These reactance coils take the form of three single-phase coils, wound upon laminated cores with an air-return circuit, the coils being immersed in oil and provided with water cooling tubes. This form of reactance was chosen, as the coreless type wound upon concrete spiders was inadmissible owing to the large amount of structural steel work in the station which would become heated due to the stray fields. The

coils will have a combined reactance at full load of 10 per cent.\* under the very worst conditions. Thus the current rise on short circuit will not exceed ten times the normal full load current.

In a similar manner, external reactance coils are being provided in each of the six turbo-generator circuits, which, with the internal reactance of the machines themselves, provide a total reactance of from 12 to 13 per cent., sufficient to limit the instantaneous short circuit to a figure not exceeding seven to eight times normal full-load current.

The machines at present are controlled by reverse-current relays which have not in every case proved satisfactory, and in order to disconnect a machine on the development of a short circuit, and before there has been time to damage the windings materially, balanced current relays will be provided on each machine circuit, with an additional inverse time relay to trip on heavy overloads.

As an additional precaution, and to prevent damage being done whilst a crippled machine is being shut down and is still running owing to the inertia of the revolving parts, short-circuit switches will be provided for short-circuiting the fields of the exciters. These switches will be automatically operated whenever the above-mentioned relays trip.

In addition, various other apparatus of a minor character will be provided, but the most intricate part of the work will be the safe substitution of the new apparatus for the old, in a station normally running twenty-four hours per day, and to enable this to be done various expedients have been devised.

\* That is to say, at full load current, the voltage across the reactance will be 10 per cent. of the voltage per phase: in this case 380 volts, as the voltage between phases of the (star-connected) generators is 650.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,355.

Ventilation is required in a static transformer chamber to keep the transformer as cool as possible. Show how the size of openings is determined, how the difference in level between inlet and outlet louvres will effect the size, and how the cubic contents of the chamber affects the question. Assume two 200 k.v.a. oil-cooled transformers in a chamber 10 ft. by 8 ft. by 12 ft. high. Calculate the size of nett opening required, and show the difference if a chimney is built to a height of 20 ft. above ground.—"AIR SUPPLY."

(Replies must be received not later than first post, Sept. 18th.)

### ANSWERS TO No. 1,353.

A three-phase induction motor with squirrel-cage rotor runs clockwise. Another similar motor, from the same makers, runs anti-clockwise; both are coupled up to a star delta switch, and to same sketch, which is standard. Having a quantity of these

motors running, it is desired not to change over the mains at the starter. Can the right rotation be obtained by altering any of the six connections at motor end, and run satisfactorily with load?—"MOTOR."

The first award (10s.) has been made to "H. J. E." for the following concise reply:—

Assume first, for the connections as shown in Fig. 1, that the motor starts up, and runs in the wrong direction. In order to alter the direction of rotation, the ends of two of the phases must be changed over, as in Fig. 2,

Fig. 1.

Fig. 2.

Fig. 3.

where ends 1 and 3 of phases 1,2 and 3,4 have been interchanged. Moreover, in order that the connections for the running position of the switch shall be correct, the star ends 2 and 6 of phases 1,2 and 5,6 must be changed over. This is shown by the full lines in Fig. 3; the dotted lines indicating the old connections.

The second award (5s.) has been made to "W.R.S.," whose reply, slightly abbreviated, is as follows:—

The normal connections are shown in Fig. 4. The stator windings A, B, C, are connected to fixed fingers, and when these fingers are engaged by the movable contacts along the line s, the windings are star-connected, as in Fig. 6, the fingers 4, 5, 6, being connected together to form a neutral point. When the contacts engage along the line d, the windings are connected in delta, as in Fig. 7. Reversal of rotation can be secured by changing the connections, as

Fig. 4.

Fig. 5.

Fig. 6.

Fig. 7.

Fig. 8.

Fig. 9.

shown in Fig. 5. The winding A is disconnected from its neutral-point finger 4 and connected to the neutral-point finger 5. The leads from the winding B are crossed; one goes to the neutral-point finger 4, and the other to the finger 7, to which the winding C was previously connected. The winding C is connected to the finger 8 in place of the winding B. With the switch in the position s, the windings are star connected, as in Fig. 8, and in the position d they are delta connected, as in Fig. 9. The change of connections is equivalent to interchanging phases 2 and 3 at the switch. If the switch employed is of a different type, the connections will be similar, and the necessary changes may be traced easily from Fig. 5.

HAVE THE  
BEST!

IGRANIC ELECTRIC CO. LTD.  
LONDON

Works:  
BEDFORD

### ELECTRIC TRACTION NOTES

A report on a recent tramcar accident in Newcastle has just been issued by Lieut.-Col. P. G. Von Donlop. While a car with a handbrake, which, owing to a broken link in the chain, could only be worked from the rear end, was being taken to the car-sheds, it got out of control and ran into a car ahead of it. Owing to the trolley having been taken off the line, the magnetic brake was inoperative, and the car started away from rest on a gentle incline, and the handbrake was not applied by the conductor, nor did the driver exercise any supervision on the conductor's action. The report points out the advisability of the Westinghouse magnetic slipper brakes being workable by hand as well as electrically.

An entirely new system of electric traction will be put into operation on the Norfolk & Western Railway, West Virginia, U.S.A., next January. Current will be supplied to the locomotives at 11,000 volts, 25 cycles, and a combination of a transformer and a rotating induction machine on each locomotive will convert this to two-phase 750 volts for the motors, which will be of the normal synchronous polyphase type without commutators. There will be four motors on each locomotive, with a total continuous rating of 1,300 h.p. at fourteen miles per hour. Each motor will have windings for producing either four or eight poles, giving two synchronous speeds of twenty-eight and fourteen miles per hour respectively. The wound rotors will give, further, a synchronous speed of seven miles per hour, with cascade connection, and allow of resistance being inserted for starting and for intermediate speeds. Two of these 130-ton locomotives will be used for each train of 3,250 tons weight. These trains carry principally coal from the Pocahontas coalfield. The motors will be geared in pairs through a jack-shaft crank and eccentrics to the driving wheels, the gear ratio being 18 to 85, and the driving wheels 62 in. in diameter. The contract with the Westinghouse Co. provides for twenty-six such locomotives, together with track equipment, transformer substations and 27,000 kw. in generating plant. These polyphase motors were chosen as against single-phase commutator motors on account of space limitations and lower cost, and the possibility of regenerative and safer braking on the heavy down grades.

The single-phase commutator motor designed by Mr. F. F. W. Alexanderson, of the General Electric Co., U.S.A., some particulars of which were given in a paper before the American Institute of Electrical Engineers in 1908, has given such satisfaction on motor coaches of the New York, New Haven & Hartford line, that new equipments of the same design have been ordered. The motor is fully described in an article by Mr. Alexanderson himself in the *Elektrotechnische Zeitschrift* of September 4th. It is a repulsion motor at starting. The heavy starting current is induced in the rotor, this reaching 1,200 amps. with a current of only 500 amps. in the contactor circuit. After a certain speed is reached, the windings are changed over to a combined series-repulsion connection, giving a better efficiency at high speeds. These motors are designed for 25-cycle operation, and it is stated that at this frequency the life of the brushes is as good as is obtained with a normal direct-current traction motor. The rotor acts as a ventilating fan, sucking air in through openings in the stator, and blowing it out at the commutator end. This method of cooling is said to keep the motor both cooler and cleaner than that of forced ventilation from outside. A locomotive with four 400-h.p. motors of the same design has just completed a several months' test satisfactorily.

The twelfth Annual Conference of the Municipal Tramways Association will be held at Sheffield on Sept. 23rd to 26th. On Wednesday, 24th, after the reception by the Lord Mayor, Mr. A. R. Fearnley will deliver his presidential address, and Papers will be read on Platform Fare Collection, by Ald. S. Flint (Leicester), and on Maintenance of Paving, by Councillor W. C. Fenton (Sheffield). The Paper down for the Thursday

is "Urban Passenger Transport," by Mr. J. B. Hamilton, General Manager Leeds Tramways. Visits to works will be paid in the afternoon, and the annual dinner is fixed for the evening.

With reference to the note on page 493 of our issue for August 28th, a revised scale of wages for motormen and conductors upon the Ashton Corporation tramways and the Stalybridge Joint Board's lines has been agreed upon, and the long dispute between the employees and the Corporation has now come to an end.

The Special Committee recently appointed by the Bristol Corporation to consider as to whether they should take over the Bristol Tramway Co.'s undertaking has called in Mr. J. B. Hamilton and Mr. J. F. C. Snell to advise them on the matter. As the result of the report of these two gentlemen, the Committee recommends the Corporation to apply to Parliament for powers to work the Company's undertaking if it should decide subsequently, as it may do, to acquire it.

### TELEPHONY AND TELEGRAPHY (INCLUDING WIRELESS)

The accounts of the Pacific Cable Board for the year ended March 31st, 1913, which have just been published, record a total expenditure of £200,170 (including an annuity payment for the replacement of capital of £77,545, a contribution of £2,048 to a provident fund, and £30,000 transferred to cable repair, reserve and renewal fund), and the receipts were £167,901 (of which £166,027 were actual traffic receipts), to which must be added the Government grant in aid of £27,645 and £18,782 brought forward from last year. There was thus the slightly lower balance of £14,157 to be carried forward. The aggregate capital expenditure now stands at £1,993,534. The report states that the cable and landline extensions described in last year's report between Australia and New Zealand have been duly completed by the India Rubber, Gutta Percha and Telegraph Works Co. and Siemens Bros. & Co., at a cost of about £177,730, which sum was drawn from the renewal fund. New electric light and refrigerating plant is being installed at Fanning Island. Some slight readjustments of tariff have been made, and in all 2,670,575 words have been dealt with in the messages transmitted during the year. The Hon. Thomas Mackenzie, High Commissioner for New Zealand, has been appointed to fill the vacancy on the Board caused by the retirement of Sir W. Hall-Jones, and Mr. A. S. Baxendale, London Manager and Secretary, has resigned his position, but the vacancy had not yet been filled at the date of the report.

It is stated that of the £50,000 voted by the Australian Commonwealth Government for the construction of wireless telegraph stations in Australia, £40,000 has already been expended. Stations have already been completed, and business is being transacted at Melbourne, Sydney, Fremantle, Adelaide, Hobart, Brisbane, Thursday Island, Port Moresby, Rockhampton, Cooktown, Geraldton, Mount Gambier and Esperance. A number of others are nearing completion.

In a few months' time it is expected that the Post Office will be opening a full automatic telephone exchange in Darlington which will have an equipment of 800 lines, this being supplied by the Western Electric Co.

In New Zealand automatic telephony is also making considerable progress. The New Zealand Government has accepted the Western Electric Company's tender for full automatic telephone exchanges in the chief towns. At Wellington three central exchanges will be erected successively for 1,300, 600 and 2,800 lines, and in addition there will be three sub-exchanges. At Auckland the exchanges and sub-exchanges will total 6,810 lines; in Blenheim, Hamilton, and Oamaru 600-line exchanges will be erected, and at Masterton an 800-line exchange. These will all be on the Western Electric Company's own system, similar to the one which is being equipped in this country at Darlington as mentioned above.

## "ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

### Specifications Published September 4th, 1913

A full list of these was published in our last issue. The following are abstracts of some of the more important specifications.

Names in italics indicate communicators of inventions from abroad.

11,479/12. **Alarms for Wireless Stations.** W. H. SHEPARD and A. E. McKECHNIE. The alarm is constructed so that an audible signal is given when a message is about to be received, but which is inoperative during the reception of the message. This is provided for by the connections to the telephone switch arm. A metal ball or pivotted weight is normally held up by an electromagnet which, when the message is signalled, is released, but is returned when the telephone switch hook is moved. Three figures.

18,371/12. **Mercury Vapour Lamps.** B.T.-H. Co. (*G. E. Co., U.S.A.*). A silica envelope of limited volume free from idle condensing space, contains a solid anode and a mercury cathode. Some liquid mercury is contained in a pocket near the anode, so as to be vapourised by it. Five figures.

18,422/12. **Alarm Signals for Wireless Stations.** J. T. SIBLEY. Alarm signals are sent only when required, depending on the length of the signals transmitted. The alarm circuit is closed by a solenoid whose action is retarded by a dash-pot or brake for a predetermined time, equal to the length of the alarm signals chosen. Two figures.

18,444/12. **Starting and Lighting System for Automobiles.** W. E. LAKE (*J. B. M. Elec. Co., U.S.A.*). The dynamo has two armature windings and a subdivided shunt field winding and an opposing series winding. For engine starting one armature winding is used, and for running as a dynamo the other winding is used. Control is effected through regulating vibratory switches and hand switches. One figure.

19,054/12. **Heating Elements.** C. R. BELLING. The resistor is wound on a former of china clay or other fireproof material with notched flanged edges, so that an air space exists between the wire and the former. The former is made with ribs at the back for strength, and it may be mechanically strengthened by an embedded crimped iron wire. Distance pieces between the edges may also be provided. Three figures.

19,064/12. **Thermal Storage Ovens.** H. J. PIPER and R. A. BRIDGWATER. The oven is made airtight and the double walls contain slag wool or a similar bad heat conductor. Metal masses heated by radiators in the walls have sufficient heat capacity to maintain a cooking temperature for a considerable time after the current is cut off. Six figures.

22,419/12. **Tirrell Regulators.** A. A. TIRRELL. A contact lever actuated by a coil energised from the circuit to be regulated is provided. This lever is connected to another lever which is oscillated by a coil, not directly dependent on the variations in the exciter circuit, so as to engage and disengage the contact lever and its fixed contact. Two relays are controlled by the regulator. One of these varies a shunt to a resistance in the exciter field circuit, and the other controls the main coil of the regulator. Five figures.

26,809/12. **D.C. Circuit Breakers.** BRITISH WESTINGHOUSE Co. The trip-coil of a D.C. circuit-breaker is connected in series with a condenser, and as a shunt to the circuit to be protected. Two figures.

28,042/12. **Multiplex Wireless.** S. D. WILLIAMS. In a non-synchronous system of duplex, duplex, or multiplex wireless telegraphy or telephony, a continuously rotating commutator with sets of contacts for putting the aerial in direct communication for periods of equal duration alternatively with the transmitter and receiver is used. One figure.

1,948/13. **Warning Signals on Railways.** R. W. PEARSON. On the approach of a train to a distant signal a bell is rung in the signal cabin or at a level crossing. A bell and visual signals may also be provided in the cab of the engine. The switch controlling the alarm circuits is actuated by the wheels of the train. Five figures.

5,040/13. **Wireless Transmitters.** C. SHOU. The signals sent out by a transmitting station are controlled over a telegraph line by a number of relays of the kind in which an iron armature is retained in its inoperative position by residual magnetism, and can be released by weak telegraphic currents. These currents are distributed to the relay through commutators, so that each single relay has a longer time for the performance of its functions than if a single relay were used.

10,154/13. **Telephone Relay.** F. MAJORANA. The telephonic currents pass through an elastic conductor stretched across a magnetic field. The resulting movements of this conductor produce changes in a microphonic contact or in the resistance of a liquid jet through which the main circuit to be controlled is closed. It is anticipated that this relay may also be used with oscillatory systems in wireless telephony. One figure.

### Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25, Southampton Buildings, London, W.C., at the price of 8d. each, post free.

Summaries of some of the more important of these patents will appear in our next issue.

**Arc Lamps:** BALFOUR and HITCHEN, 19,264/12; B.T.-H. Co. (*G.E. Co., U.S.A.*), 27,526/12.

**Distributing Systems, Cables and Wires, Insulating Materials, &c.:** B.T.-H. Co. (*G.E. Co., U.S.A.*) [Motor control] 16,806/12 and 22,664/12; HANDCOCK, DYKES and DUDDELL [Switchgear and signals operated by resonance] 6,772/13; W.E. Co. (*W.E. Co., U.S.A.*) [Flexible conductors] 10,164/13; FRANZ [Control of series-connected apparatus] 15,502/13.

**Dynamos, Motors, and Transformers:** BULLOCK [Convertors] 19,000/12; GIRVIN [High-pressure D.C. dynamos] 22,270/12.

**Electrometallurgy and Electrochemistry:** GIULINI [Aluminium nitride production] 25,874/12; JOHNSON (*Deutsche Gold and Silber-Scheide-Anstalt*) [Alkali metal production] 1,933/13; LOBECK [Milk sterilisation] 14,249/13 and 14,256/13.

**Heating and Cooking:** GEB. SIEMENS [Non-metallic heating elements] 7,932/13.

**Ignition:** RILEY [Spark plugs] 23,404/12.

**Incandescent Lamps:** WESTINGHOUSE METALLFADEN GLUHLAMPENFABRIK [Tungsten and molybdenum wire filaments] 3,162/13; A.E.G. [Lamp-manufacturing machines] 14,433/13.

**Instruments:** COPLANS [Liquid conductivity] 19,113/12.

**Switchgear, Fuses and Fittings:** POLLAK [Pressure regulators for variable-speed generators] 16,782/12; KLEIN [Snap switches] 19,073/12; STERN and BRITISH EVER-READY ELEC. Co. [Switches for hand lamps] 19,451/12; B.T.-H. Co. and WATSON [Automatic dynamo regulators] 26,597/12; SIEMENS DYNAMO WORKS and BOLTON, 27,874/12; HADDAN (*Ludenschneider Metallwerke A.-G.*) [Swan contacts] 29,372/12; CLEMENS and MONARCH REFILLABLE FUSE Co. [Refillable fuses] 3,573/13.

**Telephony and Telegraphy:** GIRARDEAU [Indirect excitation of oscillatory circuits] 11,703/12; AUTOMATIC TELEPHONE MFG. Co. (*Automatic Elec. Co., U.S.A.*) [Signalling] 19,255/12; AKT. L. M. ERICSSON & Co. [Trunk line switchboard clock control] 11,658/13; DUBILIER [Production of alternating or pulsating currents] 16,917/13.

**Traction:** TELLOW [Trolley collectors] 16,549/12; VON KRAMER [Traffic regulation and control] 19,467/12; TARRANT and SYKES [Signalling] 10,063/13.

**Miscellaneous:** DAVIES [Clock movements] 18,654/12; BRYAN and MOUNTFORT [Controlling valves] 19,203/12; STERN and BRITISH EVER-READY ELEC. Co. [Portable lamps] 19,318/12; SEVERY and SINCLAIR [Pulsation timing devices for electrically-driven musical instruments] 19,870/12; B.T.-H. Co. (*G.E. Co., U.S.A.*) [Vacuum glass containers with sealed-in conductors] 23,775/12; SNOOK and KELLY [X-rays] 24,046/12; WATKINS [Adjustable condensers] 2,238/13; A.E.G. [Clocks] 6,934/13; SIEMENS SCHUCKERT [Regeneration of transformer oil] 8,130/13.

The following Specifications are open to inspection at the Patent Office before Acceptance, but are not yet published for sale.

**Dynamos and Motors:** WHITESIDE [Motors] 18,178/13.

**Ignition:** RENAULT [Engine self-starter] 18,252/13.

**Incandescent Lamps:** PODSZUS [Manufacture from refractory material of parts of incandescent lamps] 18,323/13.

**Switchgear:** SIEMENS-SCHUCKERT, 17,532/13.

**Miscellaneous:** SNOOK [X-rays] 16,853/13; MÖLLER [Separation of suspended particles from gases] 18,357/13; BRUNS [Remote control of valves] 18,526/13.

### Grant of Patent Allowed

16,821/12. **Sewing Machine Lighting.** J. M. WALLWIN. The grant on this application, though opposed, has been allowed.

### Expired Patents

The following are the more important Patents that have become void through non-payment of renewal fees.

**Distributing Systems, &c.:** JOHNSON-LUNDELL ELEC. TRACTION Co. (*R. Lundell, U.S.A.*) [Control of compound wound motors for overbalanced lifts, &c.] 11,304/03; SIEMENS DYNAMO WORKS and H. B. POYNTER [Speed control of polyphase induction motors using auxiliary motor-generator] 11,873/07.

**Dynamos, Motors, and Transformers:** B.T.-H. Co. (*G.E. Co., U.S.A.*) [Traction motor field magnet spools] 11,444/04; J. B. BROOKS and F. H. ALSTON [Induction coils] 11,170/08.

**Electrochemistry:** G. J. ATKINS [Cells and electrodes] 11,470/04.

**Instruments and Meters:** M. KALLMANN [Calibration] 28,049/06.

**Traction:** W. P. THOMPSON (*W. H. Arnold, U.S.A.*) [Bearings for trolley wheels] 11,056/08.

**Miscellaneous:** S. O. COWPER-COLES [Electroplated lamp reflectors] 12,005/07; W. S. STELJES [Secondary clocks] 25,577/08.

## LOCAL NOTES

**Carlisle: Electricity Undertaking.**—The late City Electrical Engineer, Mr. S. T. Allen, has, at the request of the Electricity Committee, issued a statement upon the electricity undertaking for the year to March 31st, 1913. In this he points out that although the net profit is much lower than in the previous year, a large amount of capital expenditure has been charged to revenue, including £1,560 for a new switchboard. Nevertheless, the reduction in the net profit was only £1,234, in spite of other items of capital expenditure, in addition to the one mentioned above, being charged to revenue. The working expenses were the lowest on record, and only in one item has there been any increase, viz., that of fuel, which went up from 0.22d. to 0.23d. per unit. The revenue account showed an increase of £1,438, notwithstanding that the average price received per unit sold had gone down from 0.76d. to 0.72d. During the year three miles of new mains were laid.

**Hastings: Street Lighting.**—A uniform charge of £5 14s. each per annum has been agreed upon with the Electric Lighting Committee for those public lamps containing two incandescent burners.

**Hobburn: Fusing of Cables.**—The Board of Trade is to hold an inquiry into an explosion which took place a short time ago, through the fusing of an electric cable, which resulted in a fatal accident. Since that accident, other complaints have been made by residents along the routes of mains as to strong smells of bitumen in their houses, which, it is alleged, are due to the electric mains.

**King's Lynn: Electricity Accounts.**—There was a gross profit of £3,790 upon the electricity undertaking last year, and the net revenue account, including £2,038 from the previous year, was £5,828, after meeting capital charges and transferring £300 to relief of rates. The balance of £2,388 is carried forward.

**Leeds: Purchase of Roundhay Co.**—The Finance Committee propose to purchase the Roundhay & District Electric Lighting Co. at a cost of £12,390, plus £500 for liquidation purposes, the taking over of the Company's liabilities, and the making good of the Company's overdraft at the bank, making a total expenditure of between £16,000 and £17,000. When the matter came before the City Council last week, objection was taken to the proposition on the ground that the Electricity Committee had not been consulted, and in order to allow this to be done the recommendation was withdrawn for a month.

**Middleton: The Electric Power Co.**—The Corporation has agreed to the Lancashire Electric Power Co. supplying the Calico Printers' Association, Ltd., with power. It is satisfactory to note that the Corporation has taken up the attitude not often adopted under similar circumstances, that, as they themselves are unable to supply this consumer, who is in their own area, they think it their duty to allow the Power Co. to do so.

**Portsmouth: Electricity Accounts.**—After meeting capital charges, there was a net profit of £3,112 on the working of the electricity undertaking last year. Of this amount £2,500 has been transferred to relief of rates, and £500 to reserve. The number of units sold was 3,780,860.

**Redditch: Position of Electricity Undertaking.**—As reported in our columns, a special committee of the Corporation a short time ago made a special investigation into the position of the electricity undertaking, and made certain recommendations. The newly appointed Engineer has now informed the Committee that there is no stand-by machinery, and that a breakdown of the turbine at any time would mean a total failure of the supply. This report has once again disturbed those members of the Council who are opposed to the undertaking being retained, and notice has been given of a resolution calling upon the Clerk to convene a town meeting to consider the advisability of selling the undertaking, in view of the necessity for further capital expenditure as revealed by the Engineer's report, and also in view of the heavy losses which the undertaking has involved during its fourteen years' existence.

**Stirling: Proposed Purchase of Electricity Undertaking.**—With reference to the recent notes in these columns regarding the proposal of Messrs. Balfour Beatty & Co. to purchase the electrical undertaking, and to convert the horse tramways to electric traction, this firm has now been asked to submit details of their offer.

**West Hartlepool: Waste Heat Power Station.**—All the consumers on the mains of the Corporation have now been transferred to the new waste heat power station.

## TENDERS INVITED AND PROSPECTIVE BUSINESS

## Generating Stations, Sub-Stations, Mains, &amp;c.

**Bacup.**—A loan of £1,800 for additional H.T. feeders is to be applied for.

**Batley.**—Two new substations are to be built.

**Braintree.**—The Council has appointed a consulting engineer to report upon an electric lighting scheme.

**Cardiff.**—A loan of £30,500 is to be taken up chiefly for new turbine plant at the Roath power station.

**Carlisle.**—An expenditure of £4,300 in connection with the H.T. supply has been sanctioned.

**Eastbourne.**—A loan of £3,000 for additional mains is to be applied for.

**Ilkley.**—Complete power-station equipment. Consulting Engineer, Mr. George Wilkinson. October 6th. (See advertisement on another page.)

**Leek.**—Various cable extensions are to be made.

**Lurgan.**—The Council has under consideration a report by a consulting engineer upon an electric lighting scheme.

**Plymouth.**—An inquiry has been held concerning a loan of £5,500 for extensions of the plant at the electricity works.

**Port Elizabeth.** Considerable extensions are to be carried out to the electrical undertaking. Their urgency is so great that, owing to the absence through illness of the Council's Electrical Engineer, a temporary engineer is to be engaged to take charge of the extension scheme, says the *British & South African Export Gazette*.

**Royton.**—Mr. S. W. Newington, Chief Electrical Engineer to the Oldham Corporation, has reported upon an electric supply scheme for this district.

**St. Anne's-on-Sea.**—The L.G.B. has sanctioned a loan of £3,000 for mains and services.

**Salford.**—A loan of £2,000 is to be taken up for the conversion of a portion of the three-phase bulk supply at 6,600 volt to 3,000 volt two-phase supply.

**Teignmouth.**—Mr. E. M. Lacey has been retained to report upon the supply of electricity in Teignmouth and Shaldon.

**Warrington.**—Plant extensions.

**Wigan.**—One 1,500-kw. turbo-alternator, jet condenser and pipework. Borough Electrical Engineer.

**Wolverhampton.**—Two electrically-driven centrifugal pumps are to be installed at the waterworks at an estimated cost of £650.

**Worcester.**—A recommendation by the Electricity Committee to instal a wet air filter plant for the 1,500-kw. turbo-alternator at the power station has been confirmed. This decision is the direct outcome of the discussion at the I.M.E.A. Conference this year.

## Wiring

The following particulars relate to new buildings about to be erected, or important alterations and extensions in existing buildings. Wiring contractors are recommended to make inquiries to ascertain whether electrical work will be required.

**Battle.**—With reference to the note on page 496 of our last issue, notice has been given by one of the Guardians to rescind the resolution authorising the installation of electric lighting at the workhouse.

**Bridgwater.**—Enlargement of hospital (£5,000).

**Cheltenham.**—New municipal offices.

**Dublin.**—Cinematograph theatre in Henry Street. Architect, B. Crewe, 75 Shaftesbury Avenue, London.

**Eastbourne.**—Electric lighting of workhouse.

**Halifax.**—New cinematograph theatre.

FOR  
STEAM JOINTS  
USE

JOHN HUDSON & CO.'S SUCCESSORS, Mansell St., London, E.

**Leigh (Lancs.).**—Secondary School.  
**Malvern.**—New elementary school.  
**Manchester.**—Extensions to Education Offices in Deansgate (£5,000).  
**Sheffield.**—Extensions to Town Hall (£42,800).  
**Stockport.**—Trades hall. Architects, Swann & Stockton, St. Peter's Chambers.  
**Swansea.**—New nurses' home (£6,500).

### Miscellaneous

**Australia.**—Eighteen flame arc lamps and accessories are required by the Victorian Railway Commissioners.—The New South Wales Government Tramways require thirteen 600-volt D.C. motors with field rheostats.—A common battery multiple switchboard and eight automatic switchboards are required by the Deputy Postmaster-General, Melbourne. Further particulars, 73 Basinghall Street, London, E.C.—The City of Melbourne requires 9,147 yds. of lead-covered cable, and three 250-k.v.a. three-phase transformers. Messrs. McIlwraith, McEacharn & Co., Biliter Square Buildings, E.C.

Tenders are invited for the overhead electrical equipment and overhead transmission mains for the Melbourne suburban railways. (See advertisement on another page.)

**Greece.**—A 10-ton and a 6-ton electric crane is required for the docks at the Piræus. Chairman, Harbour Board. Sept. 30th.

**London: Mile End.**—A twelve months' supply of electrical fittings for Guardians. Clerk, Bancroft Road, Mile End.

**New Zealand.**—A.C. voltage regulators for 3,000-volt and 400-volt circuits by the Dunedin Town Council. Town Clerk, Nov. 12th. Further particulars, 73 Basinghall Street, E.C.

### TENDERS RECEIVED AND ACCEPTED

**Bacup.**—The tender of Messrs. W. T. Glover & Co. has been accepted for 4,000 yds. of 0.1 sq. in. cable.

**Dundee.**—A contract for converting machinery has been placed with Bruce Peebles & Co., at £1,500, the cable contract in connection therewith having been given to the British Insulated & Helsby Cables, Ltd.

**Manchester.**—The following tenders have been accepted:—Cable, W. T. Henley's Telegraph Works Co., Callender's Cable & Construction Co., and Johnson & Phillips; water-softening plant for the Stuart Street station, the Kennicott Water Softening Co.

**Peterborough.**—The tender of Messrs. Crompton & Co. has been accepted at £576 for a switchboard.

**South Africa.**—The *African World* states that the A.E.G. Electric Co. of South Africa has received a contract for the entire equipment of the new power house which is being erected by the Stellenbosch municipality.

**Torpoint.**—An offer by the local electric light company to supply 50-c.p. lamps for street-lighting purposes at £2 5s. per lamp per annum has been accepted for a period of five years.

### APPOINTMENTS AND PERSONAL NOTES

Mr. R. P. Brousson, General Manager and Engineer to the Great Northern & City Railway Co., has severed his connection with the undertaking on its acquisition by the Metropolitan Railway Co. We understand that Mr. Brousson will in future be associated with Messrs. S. Pearson & Son, the large firm of contractors, in connection with a number of electrical undertakings with which that firm is now concerned.

Mr. S. Boys, who for the past two-and-a-half years has held the position of Supplies Manager to the Sheffield branch of Messrs. Siemens Bros. Dynamo Works, Ltd., and has been associated with the firm for over ten years, is resigning this position to take up an appointment with the Edison & Swan United Electric Light Co., Ltd., where he will take charge of their London business.

The salary of Mr. H. F. Friederichs, Chief Electrical Engineer to the West Hartlepool Corporation, has been increased by £40 to £450 per annum.

After some discussion, the maximum salary of Mr. F.

Garside, Borough Electrical Engineer, Aldershot, has been increased from £300 to £350 per annum.

Mr. R. M. Carr, Borough Electrical Engineer at Leek, has resigned on receiving a more important appointment elsewhere. Applications are to be invited for the appointment of a successor to Mr. Carr at a salary of £225 rising to £275 per annum.

Mr. J. S. Smith, Charge Engineer at the Burton-on-Trent electricity works, has resigned. A successor is to be appointed.

### MISCELLANEOUS BUSINESS NOTES AND TRADE ANNOUNCEMENTS

**Price of Copper.**—Messrs. G. Smith & Son, of 5 Philpot Lane, E.C., inform us that the price of electrolytic copper bars, c.i.f. port of arrival, quoted on Tuesday night, was £77 5s. to £77 15s. (Last week, £74 to £74 10s.)

**Rapid Delivery of Osram Lamps.**—The General Electric Co. tell us of a case of extremely quick delivery of some lamps which were called for on June 4th and reached their destination at Kalgoorlie (370 miles inland in Western Australia) by July 12th, thus covering 10,750 miles in thirty-eight days, an average of about twelve miles per hour for the whole distance.

### COMPANIES' DIVIDENDS, REPORTS, MEETINGS, &c.

**British Electric Transformer.**—An interim dividend at the rate of 6 per cent. per annum less tax has been declared on the ordinary shares for the past year.

**Clyde Valley Electrical Power Co.**—At the half-yearly meeting last week a net profit of £25,907 was reported for the June half year. It has been decided to transfer £12,500 to depreciation, bringing this fund to £68,890. Contracts are in hand for an increase in the connections, bringing them to 6,438 h.p.

**The I.M.E.A.**—The Proceedings of the 1913 Convention of the Incorporated Municipal Electrical Association have now been published, and contain, as usual, the papers and discussions in full, as well as the Council's Report and list of members. In addition to the Proceedings of the Convention, the volume contains a Paper by Mr. A. M. Reid, Chief Accountant to the Dundee Corporation Electricity Department, upon "The Reliability of the 'Total Cost Per Unit Sold.'" In this Paper is discussed some possible reasons for the somewhat wide difference in the costs of various undertakings of a similar size and working under similar circumstances, as revealed by the analyses of accounts published from time to time in the technical press.

**Deaths from Electric Shock.**—Two deaths from electric shock have occurred during the week. In one case a telephone employee at Kirkcaldy was engaged upon some telephone wires in Strathore Road on a pole which also carries the Fife Electric Power Company's 8,000 volt cables. Whilst carrying out his work, his head came into contact with the power cable, and he received a fatal shock. In the other case, an electrical assistant in the works of Messrs. Stevenson & McKellar, of Pollokshaws, by some means received a fatal shock from an electric motor.

**Osram Lamps.**—The Osram Lamp Works, Ltd., last week applied before Mr. Justice Astbury, sitting as the vacation judge, for an injunction to restrain Messrs. Glenn & Co. until the trial or further order, from an alleged infringement of their patents. For the defence it was claimed that there was evidence to show that the filament in the lamps in question was not a squirted filament but a drawn filament. Mr. Justice Astbury decided that he could not grant an interim injunction, but the defendants undertook to keep an account of the lamps sold pending the action.

**COMPOUND DYNAMO** wanted, 110 volts direct, 50 amperes. AILSA CRAIG MOTOR WORKS, Chiswick.

**PLATINUM UTENSILS, SCRAP, LAMP TOPS.**—Best prices given by DERBY AND CO. LTD., 44 Clerkenwell Road, London, E.C. N.B.—Platinum Sold.

**WANTED.**—Old electric lamp tops. Scrap Platinum, Mercury, False Teeth, Metals, Rubber, Cable. ATLAS Co., Umfreville Road, Harringay, N.

### SUMMARY

SOME notes on the arrangements for the next session and other matters relating to the Universities and Technical Colleges are given. (Page 521.)

THE meeting of the British Association at Birmingham commenced with Sir Oliver Lodge's presidential address last Wednesday, and the work of the various sections started on the following morning. Prof. Kapp's address to the engineering section dealt with electric traction on main line railways. He expressed the opinion that there was little probability that the high-pressure D.C. system could beat the single-phase system, and none whatever that it would beat the three-phase system. There was also a discussion on fuel in the same section, and in the chemical section Prof. W. M. Thornton spoke on coal-dust explosions. (Page 523.)

AN interesting Paper in the Engineering Section on Friday was read by Prof. J. T. Morris, on the cost of a year's electric cooking in a small household, and mine explosions were referred to in an evening discourse. (Page 524.)

THE principal electrical Paper on Monday was by Dr. W. H. Eccles, before Section A, on the action of wireless telegraph receivers of the loose-contact type, but on Tuesday a Paper was read by Mr. W. R. Cooper advocating a method of making heating tests of electrical machinery by short runs. Prof. E. Wilson also gave the results of some exposure tests of copper,

aluminium, and duralumin, which came out in that order as regards durability. An interesting discussion on wireless telegraph wave propagation occupied a part of Tuesday morning's meeting. (Pages 524 and 525.)

ON Tuesday, Mr. J. S. Anderson described, before Section A, a method of starting mercury vapour lamps without tilting, and in Papers before that section on Wednesday, Mr. W. H. F. Murdoch gave particulars of a magnetic susceptibility meter, and Mr. J. S. Anderson described a new method of sealing electrical conductors through glass. (Page 525.)

REPORTS were submitted during the meeting of committees on electrical standards, nomenclature, and radiotelegraphic investigations. (Page 525.)

SOME good results as regards both weight and efficiency have been obtained from a process of making new, or regenerating old, storage battery plates. (Page 526.)

A SHORT illustrated article describes a new design of switch panel for electric cranes. (Page 526.)

A NEW electric water heater, some motor-car lighting switches, and an indirect lighting fitting are illustrated on page 528.

THE electrical driving of sheet rolling mills is dealt with in our Questions and Answers columns. (Page 529.)

NEW designs of potential transformers and continuous current motor starters and a new style of glassware are referred to in articles on page 529.

WE refer to the Aisgill disaster on the Midland Railway in connection with the electric lighting of trains, and give particulars of what the Midland Railway is doing with regard to track circuit signalling and electric locking devices.—The Bristol Corporation proposes to apply for powers to work the local electric tramways.—A partly underground and partly elevated electric railway is to be constructed in Berlin. (Page 530.)

UNDER "Telephony and Telegraphy," we refer to several Papers on wireless telegraph subjects read before the British Association, including one by Dr. W. H. Eccles on the theory of the behaviour of "loose contact" receivers, and a discussion on two Papers dealing with the nature and propagation of electric waves by Prof. G. W. O. Howe and Dr. Eccles, and one on the variation with meteorological conditions of the strength of wireless signals received at Liverpool from Paris, by Dr. E. W. Marchant. (Page 531.)

THE specifications published by the Patent Office last Thursday include one for a voltage regulator, by A. Pollak; a motor control system, by the B.T.H. Co., who also patent some improvements on their Tirrill regulator, and a rectifier with condensers to prevent sparking, by A. Bullock. The patents relating to metal filament lamps include a Westinghouse patent for drawn filaments and a machine for fusing in holding wires, by

the A.E.G. Among other subjects treated are isolating switches and variable condensers. (Page 532.)

THE whole of the Carlisle electricity profits are to be handed over to the relief of rates.—Public electric lighting is to be installed at Llanidloes, following a dispute with the gas company.—Progress is being made with electric lighting schemes at Portrush, Eastwood, and Truro.—Extensions of the lighting areas of Hull and York are contemplated. (Page 533.)

HIGH and low tension switchgear is required for the Melbourne Railways, and also by the Carlisle Corporation; cables at Harrogate and Heywood; a 125-h.p. motor at Hammersmith, and an air compressor at Salford.—A loan of £30,000 is to be taken up at Oldham, and various electrical plant is required in Australia. (Page 533.)

A 6 PER CENT. dividend is paid by the Victoria Falls and Transvaal Power Co. for last year, the carry forward being £96,787.—The revenue of the Yorkshire Electric Power Co. for the June half year increased by no less than 48 per cent., the net profit being £6,971. No dividend is paid on the ordinary shares, but £4,308 are carried forward. (Page 534.)

**Unique Turbo-Generator Sets.**—Some new turbo-generators of 30,000-kw. capacity were recently ordered by the Interborough Rapid Transit Co., of New York. These large turbines are divided into two elements, a high-pressure set running at 1,500 r.p.m., and a low-pressure set fed with steam from the first set running at 750 r.p.m. By this means the temperature range in either element is reduced, and a high efficiency obtained without exceptional mechanical difficulties. The loss due to two separate generators being used is said to be more than counterbalanced by the more efficient turbine speeds. According to the *Electric Railway Journal* (New York), two separate turbine elements driving separate generators at different synchronous speeds has never been done before. On a 29-in. vacuum, 75½ per cent. of the available energy of the steam has been guaranteed to be available at the generator terminals by the Westinghouse Machine Co., which is building these units.

## UNIVERSITY AND TECHNICAL COLLEGE ANNOUNCEMENTS

THE recently issued "Announcements" for the session 1913-14 at the Northampton Polytechnic Institute (Clerkenwell, E.C.) shows that both day and evening courses in electrical and mechanical engineering, including wireless telegraphy and electro-chemistry, may be taken. The Principal of the College and Head of the Electrical Department is Dr. R. Mullineux Walmsley. The day courses commence on Monday, September 29th, and the evening classes on Monday, September 22nd. Enrolments for the latter commenced on Monday last. The engineering day courses are being continued with certain minor developments. In the evening classes departures have been made by the introduction of short courses of lectures by specialists in their various subjects. Thus, in the electrical engineering department one of the series of advanced lectures has interpolated a special course of six lectures on "Business Engineering in its Legal Aspects," by Major W. A. J. O'Meara, whilst another course has interpolated a special course of six lectures on "Secondary Batteries," by Mr. W. R. Cooper. These special courses, whilst intended primarily for those who are taking the full course, can be attended by others who are specially interested in the subject. A new departure is also being made in the section of the telegraphy and telephony in the arrangement of special classes for workmen on the maintenance and constructional staff of the Post Office, and also for the boy messengers. Special classes in submarine cable work for the employees of the various cable companies who have their headquarters in London are to be held, under the direction of Mr. J. H. Stephens, of the Eastern Telegraph Co.

The full course of study in electrical engineering at King's College, London, provides, in addition to the academic training, opportunity for practical training in works. Three-year courses are also held. These courses are arranged to be suitable for candidates for the engineering degrees of the University of London, or for the diplomas and certificates of the College. Prof. D. S. Capper is Dean of the Faculty of Engineering, and Prof. Ernest Wilson is Head of the Electrical Engineering Department. Full information as to the courses can be obtained from the Secretary, King's College, Strand, W.C.

MEMBER OF THE GENERAL PUBLIC:—Here is something from the British Association for the Advancement of Science which I can understand at any rate.

## THE MEETING OF THE BRITISH ASSOCIATION AT BIRMINGHAM

THE Birmingham meeting of the British Association commenced on Wednesday of last week with the Presidential address of Sir Oliver Lodge, which was entitled "Continuity" and dealt with some tendencies of present-day scientific thought, particularly as regards the existence of a continuous ether, and contained various speculations regarding continuity in other branches of thought. The work of the various sections started on Thursday. That of Section G (Engineering) commenced with the sectional presidential address of Dr. Gisbert Kapp.

### Electric Traction on Main Line Railways.

Professor Kapp devoted his address mainly to a survey of the present position of electric traction on railways, the best argument in favour of which was the vast amount of capital now being spent in many countries on the conversion to electrical working of main lines. He dismissed briefly as obsolete the Ward-Leonard system of single-phase transmission and continuous-current driving, and also the three-wire continuous-current system of obtaining high trolley voltage with low motor voltage, and took up in more detail the three-phase, single-phase, and continuous-current methods as now applied. In the three-phase system, largely used in Italy, the objections of complication of the double overhead wire, the danger that the motors would not share the load equally, and the inability to run without rheostatic waste at intermediate speeds, or to run at a higher than synchronous speed to make up for lost time, have been found to be of little weight in practical work. Any slight inequality in the driving-wheels of two locomotives coupled together may be compensated for by an adjustment of the slip of the motors, and in some cases, an automatic slip adjusting liquid rheostat is used controlled by a series solenoid which incidentally gives a wonderfully constant acceleration. As many as four economical speeds are obtained by pole-changing, which has now superseded the cascade connection. The main advantage of the system is the steady regenerative braking possible on down grades, which not only allows of higher safe speeds down hill, but saves as much as 17 per cent. on the coal bill. Recent designs of 2,000-h.p. three-phase locomotives weighed 30 kg. per h.p. With regard to single-phase motors, Dr. Kapp stated that the present tendency was in favour of the series rather than the repulsion motor, and mentioned the latest 2,500 h.p. locomotives of this class, designed by Behn-Eschenberg, weighing 43 kg. per h.p. These figures compare with 50 to 70 kg. per h.p. for the high-pressure C.C. system. The Deri motor, which had appeared promising, owing to its simplicity of control by brush shifting only, worked out rather heavy with the low frequencies alone possible in traction, and the Latour-Winter-Eichberg repulsion motor was only satisfactory at frequencies as high as 25 cycles. Its great advantage was its good power-factor and commutation at speeds slightly above synchronism. The line pressure on single-phase lines may be anything up to 15,000 volts, a figure likely to become standard in future, but with "high pressure" C.C. working, 1,200 volts is the maximum in America, 2,000 on the Continent, and 3,500 in England, in all cases with two motors in series. This last pressure is that used in the recent short section of the Lancashire & Yorkshire Railway equipped by Dick, Kerr & Co. Here motor coaches are used, each with four 300-h.p. motors, and the complete coaches weigh only 52 kg. per h.p. Such excellent commutation is obtained that one set of brushes lasts 50,000 miles. "From the figures quoted above," continues Dr. Kapp, "it will be seen that where motor coaches are employed, the C.C. system has an advantage in point of weight over the single-phase A.C. system. But main-line traction, including goods trains, is not going to be done by motor coaches, and if we come to large electromotives of some 2,000 to 3,000 horse-power, then this advantage is likely to vanish. No high-pressure C.C. electromotive has as yet been built for so large a power, and it is therefore not possible to make a direct comparison; but, if we may judge from the largest engines yet built for moderate-pressure C.C., there is little probability that the C.C. system for high-pressure can beat the single-phase system, and none whatever that it can beat the three-phase system." The interference with telephone lines of single-phase traction now appears to be due not to the commutator, but to the employment of open slots in the motors, and the trouble nearly ceased when rotors with semi-closed spiralled slots were used. Precautions, however, have to be taken to prevent the telephone lines acquiring a high potential. The frequency of 15 cycles chosen as standard by the Swiss Government Commission was chosen in preference to a higher figure mainly with a view to keeping down the number of poles of the motors, maintaining a good power-factor, less skin effect in the rails, and less liability to disturbance of neighbouring circuits. The address then set forth some details of the three-phase lines at work

in Italy, and the latest 2,500-h.p. single-phase locomotives now running on the Loetschberg line, and, in conclusion, mentioned the forthcoming conversion to electric traction of the Gothard line. The first section that will be converted is that between Erstfeld and Bellinzona, a length of 110 km., of which 29 are in tunnel, with heavy gradients. The Erstfeld-Airolo section will be running in four years, and the southern one a year later. Ultimately the electrical working is to be extended to Lucerne, 60 km. to the north, and to Chiasso, 55 km. to the south. Power will be taken from two water-power stations, one at Amsteg, where at first 32,000 h.p., and ultimately 60,000 h.p., will be available, and the other at Piotta for 40,000 h.p., and later 50,000 h.p. Power will be transmitted along duplicated feeders at 30,000 volts, and the line pressure will at first be 7,500 and later 15,000 volts. There are to be sub-stations at Biasca, Goeschenen, Lavorgo, and Bellinzona. Only locomotives will be used. These are to haul express trains weighing 420 tons at 50 km. per hour up grades of 2.6 per cent., which will require about 3,000 h.p. Goods trains weighing 670 tons are to be hauled by two locomotives at 23 km. per hour.

### Fuel.

An important feature of Thursday's meeting of the section was a discussion on fuel, initiated by Prof. F. W. Burstall (Birmingham).

Prof. Burstall emphasised the high thermo-dynamic efficiency of the gas engine, although he did not see much future for the gas turbine, and outlined gas and by-product production at the coal fields. There was no real rivalry, he said, between gas and electricity; both took their origin from coal, and each was capable of doing things that the other could not. Mr. W. M. Mordey and Prof. T. H. Beare looked forward to possible adaptations of the Humphry gas pump in conjunction with water turbines for driving dynamos.

A few references to electrical matters were made in some of the other Sections.

**Coal Dust Explosions.**—Mining engineers will be interested in a Paper read the same day before Section B (Chemistry) by Prof. W. M. Thornton (Newcastle) on the influence of the presence of gas on the inflammability of coal dust in air. This contained an account of a series of experiments on the sensitiveness to ignition of clouds of dust in various mixtures of gas and air, observing the minimum current required to be broken to cause an explosion. We hope to deal with this research more fully at a later date.

**Power Production.**—Reference was made in the presidential address of Prof. H. N. Dixon to Section E (Geography) to the power resources of the country, and the field of electric transmission, both in connection with water power which could thereby be used by means of the electric furnace for metallurgical processes, and in connection with power supply from the coal fields from generating stations at the pit's mouth, or possibly, as Sir William Ramsay had suggested, even without actually mining the coal.

The most important of the series of papers read before Section G on Friday morning, was that by Prof. J. T. Morris, entitled:—

### Cost of a Year's Electric Cooking in a Small Household.

Prof. J. T. Morris has taken some valuable records of the cost of electric cooking (and also lighting and heating) in a flat in Marylebone consisting of six rooms plus a kitchen and bathroom. Electric heating was not employed for the hot-water supply, but, instead of a kitchen fire for this, a small Carron coke boiler was employed, which also served to heat the kitchen in the winter and for burning rubbish. The figures represent consumption for five persons with occasional visitors. The item for heating does not comprise quite the entire cost, as a coal fire was used in one of the rooms for part of the period in question. No gas is used in the flat at all. The expenditure from July 27, 1912, to July 26, 1913, was as follows:—

	£	s.	d.
Annual "Telephone" charge	...	6	10 8
Hire of cooker at 15s. per quarter	...	3	0 0
Cooking: 2,934 units at 3d.	...	6	2 3
Heating: 2,068 " " "	...	4	6 2
Lighting: 200 " " "	...	0	8 4
		20	7 5
Coke and wood	...	4	11 0
		24	18 5

Owing largely to the reduction of the heavy work in the flat due to the suppression of the kitchen range, a saving of between £25 and £30 was made in the cost of domestic service.

A Jackson cooker was employed, having three hot plates, two for boiling, and one of lower heat for simmering purposes, one grill and a fair-sized oven, the approximate measurements being: height 38 in., width 30 in., depth 24 in. The Board of Trade units when each of the hot plates, &c., were in use individually for one hour is given in the following table:—

	No. 1.			No. 2.			No. 3.		
	Low.	Med.	High.	Low.	Med.	High.	Low.	Med.	High.
Units used in 1 hour	0.36	0.67	1.34	0.36	0.70	1.39	0.24	0.48	0.94

	Oven.			
	Grill.	One-third.	Two-thirds.	1/3+2/3rds.
Units used in 1 hour	1.34	1.06	2.11	3.17

Detailed observation of the consumption was carried out for the latter ten months of the period. For cooking, the number of units consumed weekly varied from 48 to 90 (excepting the Christmas pudding week, when it rose to 100). The weekly average during these ten months was 68.2, but it is seen from the first table that the average during the whole year was only 56.4. For lighting, an average of less than 5 units a week was consumed, and the maximum was 6.5.

A typical load curve, taken on Jan. 20th, 1913, is given below, compared with the station load curve; it is seen that

CURVES COMPARING GENERATING-STATION LOAD (CURVE A) WITH SHAPE OF COOKING, HEATING, AND LIGHTING LOAD DUE TO ONE CONSUMER (CURVE B).

the peaks do not exactly coincide, and that the addition of similar domestic cooking installations in large numbers would improve the station load curve considerably. The two curves are, of course, of different vertical scale.

In the concluding part of his Paper, Prof. Morris considered the direction in which further improvements in cooking apparatus were being made. Experience gained with his electric cooker had suggested the following:—(1) At present a rather serious obstacle in the way of reheating dishes—a common everyday need in most households—is the relatively long time taken in bringing the oven to the working temperature, and consequently the disproportionately large expenditure of energy to effect a comparatively trifling result. (2) The time taken to boil a pint of water, especially the first one in the morning when the cooker is quite cold, might be shortened with considerable advantage. (3) Cooking utensils, however perfectly flat-bottomed they may be when first supplied, appear, with ordinary wear and tear, too soon to lose this quality, so necessary for economy both in time and energy used. That these matters were receiving attention at the hands of some designers of electric cookers, he said, would be gathered from the following information which he had received since the first draft of his Paper had been made. The latest form of electric cooker, of which about a dozen are in use at the present time, have the ovens arranged so that the direct radiation from the heater is not shielded in any way, with the result that the time taken for raising the oven to the working temperature has been reduced to about one-half of what it was in the older patterns. Further, in a week or two a red-hot plate would be put upon the market which would halve the time necessary for raising cold water up to the boiling point, avoid the necessity for special utensils, and would be robust, for cold water could be poured upon it with impunity.

Professor MORRIS, after reading his Paper, added that in Birmingham heating was charged at 1d. per unit, and lighting

at 3d., whilst in addition the apparatus was not hired out, but sold on the hire purchase system. The altered conditions would make the year's cost in a similar case in Birmingham come to £33 15s. 4d., compared with the £24 18s. 5d. given in the Paper for Marylebone.

The CHAIRMAN (Professor Gisbert Kapp) mentioned the less shrinkage of meat with electric cooking, which was one of its great advantages.

Dr. J. A. FLEMING said he had carried on domestic cooking for three years, but one of its drawbacks was the irregular life of the heaters. There was also the difficulty that as the stoves were at present constructed, the heaters were not detachable, with the result that if anything went wrong, the whole oven had to be sent back to the makers for repair. As to the cost of electric cooking, he had to pay 1½d. per unit, and that put it out of court altogether for water heating. At ½d. per unit, electric cooking compared favourably with coal or gas, and none who had ever cooked electrically would want to give it up. Even at 1d. per unit it was comparable.

Professor MORRIS agreed with Dr. Fleming that the stoves should be so made that if anything went wrong it could be put right in the house at once. In Marylebone, however, the stoves were maintained by the Electricity Department, and the £3 a year included maintenance as well as hire. If anything went wrong, one had only to telephone the department, and it would be put right in two hours. He believed the hire charge of £3 was to be reduced considerably very shortly. On his particular stove also there was a spare hot plate.

**Mine Explosions.**—Means of preventing explosions in mines formed the subject of a discourse delivered on Friday evening by Sir H. H. Cunynghame. He enlarged particularly on the dust danger, and emphasised the necessity for enclosing lamps, coal-cutters, and all electrical machinery, so that they could not set fire to the dust.

The Papers read before Section G on Monday were none of them of direct electrical engineering interest. In Section A, however, Dr. W. H. Eccles read a Paper on the Contacts Used as Detectors in Radiotelegraphy. In this Paper, which is referred to more fully under "Telegraphy and Telephony," the author investigates to what extent the effects produced are due to thermo-electric action.

On Tuesday a Paper was read by Mr. W. R. Cooper on:—

#### Short Heat Tests of Electrical Machines.

Tests of dynamo-electric machinery are generally carried out extending over six hours in order to determine the maximum temperature rise. Suggestions have been made that such tests might be considerably shortened by assuming that the curve of temperature rise is a logarithmic curve. The author gives a brief account of the methods that have been proposed, and points out that the "thermal time constant," on which the behaviour of a body in heating and cooling largely depends, should be found most easily, and under less complex conditions, from the cooling curve. In order to test the applicability of the various methods, tests were made upon a 5-kw. motor-driven dynamo. The curves of temperature rise were found to be fairly logarithmic. The usual method of running a machine on test is to run on constant output with constant voltage, which necessitates increasing the input to the field coils as their resistance rises. A truly logarithmic curve can only be expected if the input of heat is at a constant rate, so that a better result would be expected if a machine were tested with constant input to the field coils, the output of the machine being constant, but at varying voltage. Actually this method of testing was not found to give an improved result. Graphical methods appear to give better results than formulæ, as the latter are very sensitive to small errors in the data. In any case only certain portions of the temperature-rise curve should be used, and any formulæ depending on the initial rate of temperature-rise should be avoided, as this is difficult of exact determination. The curve of cooling has certain advantages; only a small portion of it seems suitable for graphically determining the thermal time constant, but this quantity can be derived much more readily by the time taken for a certain percentage drop of temperature-rise. In the results given there is better agreement between the values found for the thermal time constant than for the maximum temperature-rise. It is suggested that a fair approximation to the maximum temperature-rise can often be obtained by testing for a time equal to, say, one and a quarter times the thermal time constant, deducing the value of this constant from the cooling curve, and thence the maximum temperature-rise from the heating curve.

Two or three speakers spoke upon the paper in the course of this discussion, Mr. W. M. Mordey remarking that apparently Mr. Cooper did not put forward with any very great confidence

the shortening of the test runs. Personally, he thought that too much attention was paid to the question of temperature tests. Many other questions were of far greater importance, such, for instance, as freedom from vibration, bearings, balance, &c., especially as in machines made by most good makers the temperature rise could be relied upon to be rarely in excess of the ordinary specified limits. Most methods of testing temperature were unsatisfactory. The resistance method was quite useless, and the thermometer method almost equally so. What one wanted was the temperature of the hottest part of the dynamo, and this could not be obtained by either of the above methods. Manufacturers or consulting engineers should adopt the plan of putting into every important machine in the place where tests had shown the greatest heat—as a matter of ordinary manufacture—a small platinum resistance or couple in order to enable one to determine the temperature of the hottest part of the machine. He had specified this himself, and the cost of doing so was nothing compared with the information obtained, because it enabled one to make tests as to the life of the insulating material. Prof. W. E. Marchant asked the author how he measured the temperature rise, because he had nearly always found in getting heating curves that there was a bend at the beginning of the curve. Mr. Cooper said that he used a resistance to get rid of this effect.

**Exposure Tests of Copper, Aluminium, and Duralumin.**—A Paper also read on Tuesday morning before Section G by Prof. E. Wilson described a continuation of tests upon the influence of exposure in London on the electrical conductivity of light aluminium alloys, reports of which have been made from time to time to the British Association. Each specimen is in the form of wire 0.126 in. diameter and 70 ft. long; and the percentage increases of electrical resistance after two years' exposure of high conductivity copper, commercial aluminium, and duralumin, were found to be 2.0, 4.4, and 8.2 respectively. Duralumin is a copper-manganese-magnesium alloy of high tensile strength, and exposure has apparently made it more brittle.

### Wireless Telegraphy.

After these Papers, the following three Papers on wireless telegraph subjects were read and discussed together:—The nature of the electromagnetic waves employed in radio-telegraphy, and the mode of propagation, by Prof. G. W. O. Howe; atmospheric refraction and absorption as affecting transmission in wireless telegraphy, by Dr. W. H. Eccles; and the effect of atmospheric conditions on the strength of signals received at Liverpool from Paris by Prof. W. E. Marchant, together with an account of the diurnal variations in the energy received. Further reference to these Papers is contained under "Telephony and Telegraphy" on another page.

### Mercury Vapour Lamps.

One of the Papers before Section A on Tuesday, by Mr. J. S. Anderson, described a new method of starting mercury vapour apparatus.

The tilting arrangement for starting is very often inconvenient. Messrs. John S. Anderson and G. B. Burnside have overcome this difficulty by the employment of a heating arrangement near one of the electrodes, preferably the negative. The lamp tube is provided with a small vessel near this electrode, the vessel having a re-entrant portion or recess in which a heating element, e.g., a small coil of platinum wire, is placed. The part of the tube immediately above this small vessel and its recess is constricted so that the coil may be removed at will, without interfering with the vacuum of the lamp. The heating coil of wire is connected in series or in shunt, in the latter case being provided with an automatic cut-out. An external resistance is placed in series with the lamp. Before starting, the small vessel is full of mercury, which forms a continuous connection inside the tube between the positive and negative electrodes. When the electrical current is switched on, the heating coil becomes incandescent, and the heat given off by the wire goes to raising the temperature of the vessel and its contained mercury, there being no appreciable loss by radiation into the surrounding air. Very little heat is required, because the first bubble of mercury vapour formed rises to the constricted portion of the lamp and is there caught, thus breaking the continuity of the mercury inside the lamp and starting the arc. Owing to the resistance of the mercury vapour, which is formed once the arc is started, the current is cut down to the value required for running the lamp. The platinum wire of the heating element can be made of such a thickness, and the external resistance can be so adjusted, that the wire does not emit heat when the lamp is working, but becomes incandescent when the lamp is started, the action being quite automatic.

Among the papers of electrical interest read before Section A on Wednesday were the following:—

**A Magnetic Susceptibility Meter.**—A Paper by Mr. W. H. F. Murdoch described a unipolar method of testing, with the addition of a circular coil in series with the magnetising solenoid. This coil acts upon the magnetometer needle which is lying in a neutral field of force, so that the tangent of the resulting deflection due to the magnetic material plus the coil is strictly proportional to the magnetic susceptibility. A mirror may be used to read the deflections. Such an instrument with tangent scale and pointer can be graduated to read directly the value of the susceptibility coefficient in C.G.S. units. To fix the value of  $H$ , the current is measured and the values multiplied by a constant. The theory of the instrument was given, and an example of its use for testing iron, together with a diagram of connections and curve of results.

**Sealing Electrical Conductors through Glass.**—Mr. John S. Anderson described the progress of the experiments made in conjunction with Mr. G. B. Burnside, who had devised a simple method whereby not only platinum wires, but also other conductors, such as copper wires, may be sealed through ordinary glass. The metal and glass are fused together in the usual way, and then, after the seal has cooled to about a red heat, it is immersed in a bath of oil or fat. Each immersion lasts about two or three seconds, and the seal is immersed a little further in the cooling medium at each successive immersion until it is completely cooled. For currents up to 15 amperes solid conductors may be employed, but for larger currents it is found advisable to make use of tubular conductors. Copper wires 1.5 mm. in diameter were successfully sealed through German glass, and platinum wires of 1 mm. diameter were sealed through Jena and other glasses. A copper tube, capable of carrying a current of 100 amperes, was sealed through German glass. In the case of mercury vapour lamps, platinum must be used, but a tubular form of conductor can be employed for large electrical currents, and the tubular shell filled in with copper, subsequent to the sealing process.

The following were among the reports of special committees submitted during the meeting:—

**Committee on Electrical Standards.**—The Committee has concluded its labours, and does not ask for reappointment. The admirable work done from 1862 to 1870, and from 1881 to 1912, has been published in book form (see review in *ELECTRICAL ENGINEERING*, March 13th, 1913). This year's report is very short, and relates chiefly to the new Lorenz apparatus at the National Physical Laboratory, which is now complete. By its means measurements of resistance will be able to be made "with an uncertainty of not more than a few parts in 100,000."

**Electrical Nomenclature.**—A report was also issued by the committee on the nomenclature and definitions of magnetic and electrical quantities, of which Dr. S. P. Thompson is Chairman. After a general consideration of the questions involved, the committee recommend that no multiples smaller than by 1,000 be used, and proceed to give a list of proposed symbols which differ slightly from that put forward by the International Electrotechnical Commission; the latter, although having much to recommend it, fails in some cases in details. For example, the correlation of magnetic and electrical quantities is imperfect. The committee follow the convention that specific quantities, numerical constants, and angles be expressed by Greek letters, and propose that total quantities be expressed by Roman capitals, while length, space, or volume differentials be expressed in block or heavy capitals, differentials being given the same letter as the total quantities. The problems connected with magnetic units are discussed, and the term "gauss" is favoured for the C.G.S. unit of magnetic force, and the "line" for magnetic flux. Important divergences from the I.E.C. list is the use of the block letter  $I$  for current density instead of  $\Delta$ , and  $\kappa$  instead of  $\epsilon$  for specific inductive capacity. The various quantities are discussed in detail at some length, and finally a series of proposed definitions for each is given.

**Radiotelegraphic Investigations.**—A report was also issued by the committee which is investigating the influence of meteorological conditions, &c., on wireless signals and the origin of stray waves, which is referred to under "Telephony and Telegraphy" on another page.

**Arc Lamps versus High-pressure Gas.**—The City of Strasburg has recently carried out experiments in street lighting with two kinds of flame arc lamps, inverted high-pressure gas lamps and two kinds of inverted low-pressure gas lamps. Some results obtained are given in the *Elektrotechnische Zeitschrift* of September 11th. The costs were reckoned on the basis of 1s. 8d. per 1,000 cubic feet for gas, and for electricity 1.44d. per unit until 10 p.m., and 0.48d. per unit from 10 p.m. until dawn, giving an average price of 0.83d. per unit. The total costs, including all materials and attendance per Lux, for 100 square metres per hour, were as follows:—Arc lamps, A, 0.02d.; arc lamps, B, 0.017d.; high-pressure gas, 0.036d.; low-pressure gas, A, 0.04d.; low-pressure gas, B, 0.051d. In other words, the arc lamps came out, on the average, half the cost of the gas lamps. As a result of these tests, the city authorities decided to instal arc lamps.

## BATTERIES FOR TRACTION AND VEHICLE LIGHTING

THE "Naylor" process, originally applied to regenerating old storage-battery plates (ELECTRICAL ENGINEERING, Vol. VII., p. 155, March 23rd, 1911), is now, after thorough testing, applied to the production of entirely new plates by the Naylor (Patent) Battery Co. (1 Lammermoor Road, Balham, S.W.). We understand that upwards of 120 complete batteries have now been made and have given very satisfactory results. The process which is used is patented by Mr. E. H. Naylor, and consists in cleaning the negative plates of old batteries and then in immersing them in a bath of sulphothinoyl chloride or disulphur dichloride ( $S_2Cl_2$ ). This substance is energetically absorbed by the active material with the generation of heat, and as a result the active material

FIG. 1.—DISCHARGE CURVES FOR 21-PLATE "NAYLOR" TRACTION CELL WEIGHING 29LB. COMPLETE.

actually becomes a porous metallic lead thoroughly welded to the conductor. After being subjected to heat to remove the free sulphur and chlorine, the active material is reduced electrolytically in dilute sulphuric acid, and the plates are washed and "formed." The life of any of these batteries has been found to be as much as 4,500 to 5,000 miles when used on electric vehicles.

In the case of a landaulette weighing 38 cwt. and carrying four passengers and the driver, a distance of fifty-six miles can be run with forty-five cells each containing twenty-one plates and weighing 29 lb. The capacity of the battery is between 200 and 210 ampere-hours. The discharge can be

FIG. 2.—DISCHARGE CURVES FOR "NAYLOR" RAILWAY LIGHTING CELL WEIGHING 40LB. COMPLETE.

increased to 50 amperes without hurt to the battery, and can be maintained for three hours. Allowing that the plates would cost about £34 when new, and were returned twice and regenerated for £20 each time, so that three lives of 5,000 miles are obtained, the cost per battery mile is between 1d. and 1½d. (excluding the cost of charging).

The test curves of these cells are given in Fig. 1. Each cell has twenty-one plates, and the cell, complete with acid in ebonite box, weighs 29 lb. With a discharge of 35 amperes the voltage does not fall below 1.8 volts for five hours forty-five minutes, so that the capacity is 201 ampere-hours (or 18.6 watt-hours per lb. of cell). When the discharge is increased to 45 amperes the time is only reduced to four hours, and the capacity to 180 ampere-hours, while at the 50-ampere

rate the time falls to three hours twenty-five minutes and the capacity to 170 ampere-hours.

The cells have also been found to be very efficient for vehicle lighting, and Mr. Naylor claims that the following figures show that there is no need to employ lighting dynamos for trains. In Fig. 2 are given the results of tests on a cell used for train lighting. In ebonite box, complete with acid, the weight is only 33 lb., and in a wooden lead-lined box only 40 lb. With a discharge of 20 amperes it takes six hours for the voltage to fall to 2 volts, or ten hours to fall to 1.8 volts. By increasing the discharge rate to 35 and 45 amperes the times taken for the voltage to fall to 1.8 are four-and-a-half and three hours respectively.

The low cost and weight, combined with the results obtained, would indicate that the plates made by this process will be useful in other cases than railway and car lighting and road traction; for instance, on board ship, in submarines, &c., as well as for land purposes, especially where space is valuable. So far the process has not been applied to cells much larger than those mentioned, though there is apparently no reason why this should not be done.

## IRONCLAD CRANE PANELS

A NEW form of switch-panel has recently been designed by the General Electric Co. (67 Queen Victoria St., E.C.) to meet the very exacting demands of crane work. It consists of a standard Salford switch and a distribution board mounted on a strong iron framework, together with pilot lamps and an inspection lamp plug. The switch is completely separate from the distribution board, and the main fuses are contained in the switch-case. These fuses are enclosed in separate fireproof compartments, and the case is lined with insulating material. The inspection lamp plug is connected to the top contacts of the switch, so that the crane driver can use the light irrespective of whether the main switch is open or closed. In order to afford the operator an indication of whether the power is on his controller, two pilot lamps which are provided are alight the whole time

IRONCLAD CRANE PANEL.

the switch is closed. The switch blades are interlocked with the cover of the switch, so that it is not possible to close the switch with the cover open, or to open the cover with the switch closed. Both the inspection lamps and pilot lamps are protected by fuses fixed on either side of the switch-case. Care has been taken to insure that the clearances between the fuses are adequate, and no attempt has been made to sacrifice safety to compactness. The fuses are of the Home Office pattern, and it is impossible for the hand to touch a live part accidentally whilst inserting or removing a fuse. The cables from the bottom of the main fuses can be conveyed from the switch-case to the distribution board in conduit. These panels are made for continuous and alternating-current work in sizes from 50 to 200 amperes at 500 volts.

## QUESTIONS AND ANSWERS BY PRACTICAL MEN

### RULES.

**QUESTIONS:** We invite our readers to send us questions, preferably on technical problems that have arisen in actual practice. Questions which we consider of sufficient general interest to our readers will either be replied to under "Answers to Correspondents," or replies will be invited from our readers. One shilling will be paid for the question which we select for competitive replies in this column.

**ANSWERS:** A fee of 10s. will be paid for the answer which we consider shows the greatest merit, and 5s. for the one we select as second best. Replies should reach this office within seven days of the appearance of the question. In judging the replies, importance will be attached to clearness and conciseness, as well as accuracy. The Editor reserves the right to make no award, or to accept only one reply, if, in his opinion, the answers received do not possess sufficient merit. Competitors desiring the return of their manuscripts, if unaccepted, should enclose stamped addressed envelope.

Write on one side of the paper only, and if diagrams are sent, draw them on a separate sheet of paper attached to the manuscript. Competitors may adopt a "nom de plume," but, both in the case of questions and answers, the competitor's real name and address must be sent with the manuscript as a guarantee of good faith. No correspondence will be entered into with regard to unsuccessful replies. The Editor's decision is final.

### QUESTION No. 1,356.

Work out, in terms of the rated wattage and voltage of a tungsten lamp when run at normal efficiency, the range of resistance necessary for a dimming switch in series with the lamp to reduce the candle-power to from 5 to 60 per cent. of the normal. Over what range of candle-power will the various dimming switches on the market regulate a 55-watt 200-volt lamp?—"H. T."

(Replies must be received not later than first post, Sept. 25th.)

### ANSWERS TO No. 1,354.

WHAT are the advantages gained by the adoption of electrical over steam driving for sheet rolling mills, and are there also any disadvantages? If possible, state the saving derived per ton of sheets rolled by electrical driving compared with steam driving.—"MORGAN MORGAN."

The first award (10s.) is given to "J. A." for the following reply:—
